Dutrochet, wishing to ascertain the force of the endosmotic current, employed for this purpose the apparatus which Hales and, after him, Mirbel and Chevreul had used to measure the pressure of the juices in plants. In this apparatus the force of the current is estimated by the height of a column of mercury raised by the liquid. The result of Dutrochet's experiments, in this respect, prove that, *ceteris paribus*, the force of the endosmotic current is proportional to the excess of the density of the internal liquid over that of the water; the force of the endosmotic current appears thus to be governed by the same law as its velocity. Hence it would result, supposing this law to hold good in all cases, that sugar syrup of 1.3 density would produce a current capable of raising a column of mercury of 127 French inches (3 mètres 42 centimètres), or, what comes to the same point, would be equal to the enormous pressure of four atmospheres and a half.

Various attempts have been made to account for the phenomena of endosmosis. Thus endosmosis has been attributed to the action of an electric current, developed by the contact of the two different liquids, which current is assumed to create the movement of the water through the membrane, from the positive to the negative pole, as in the well-known experiment of Porret. However, to invest this supposition with any degree of probability, it should first be proved that the contact of water with alcohol, solution of sugar, &c., causes the development of electricity; and this has not yet been done. Pousson has started another hypothesis, viz., according to him, the less dense fluid of the two penetrates the capillary tubes of the membrane, and this capillary stream, drawn downwards by the action of the water, and upwards by that of the

dense fluid, is raised into the tube by the superior force of molecular attraction possessed by the denser liquid. But this hypothesis seems equally inadmissible, if we reflect that alcohol, which is less dense than water, produces endosmosis; that a trace of sulphuretted hydrogen stops the endosmotic process; and that certain calcareous and siliceous stones, although placed in the same conditions as membranes and layers of clay, fail to effect this process. It must be confessed, therefore, that we have no satisfactory theory of the phenomena of endosmosis; we know, however, that the general conditions of these phenomena are—1. That the two liquids, or, at all events, one of them, should have affinity for the substance interposed between them. 2. That the two fluids should have a mutual affinity for one another and should, consequently, be miscible. Where one of these conditions is wanting, there will be no endosmosis. The direction of the endosmotic current is determined neither by the less nor by the more dense fluid of the two, nor by that of the two which is endowed with the greater force of ascension in capillary tubes; but it proceeds generally towards that liquid which has the greatest affinity for the substance interposed, and is most susceptible of being imbibed.

Endosmosis may be looked upon as the most important of the physical facts, with respect to its applications to the functions of living bodies. Microscopical observation has placed it beyond doubt, that in all animal and vegetable tissues, and in those fluids that are generated by the transmutation of organized and living bodies, there are invariably found, at a certain period of their formation, microscopic corpuscles of a peculiar and characteristic form, and which have been named *elementary* or *primitive cells*. These corpuscles consist of an exceedingly fine membrane, of spherical shape, enclosing a liquid, and upon the internal walls of which is found a small organized body, upon which the name *nucleus* or *cytoblast* has been bestowed. These elementary cells float at first in a liquid termed by Schwann *cytoblastema*, subsequently, when this liquid has acquired a greater or less degree of density, these cells become, as it were, incorporated in, and almost entirely blended with it. According to the respective natures of the different tissues, the elementary cells are placed more or less near to one another; the cytoblastema, or intercellular substance, forms invariably the link of union between the cells. The life of the elementary cell-forms, indubitably, the most essential part of the development and preservation of the tissues of living bodies; and, as these cells are placed in conditions favourable for endosmosis, there is no reason why this process should not take place in them. A vesicle filled with a liquid, and floating in the midst of another liquid, may imbibe the surrounding fluid and eliminate its original contents by an operation analogous to endosmosis. Few and imperfect attempts only have, however, as yet been made to study the phenomenon of endosmosis in a physiological point of view. The author has, therefore, felt called upon to endeavour to supply this deficiency, for which purpose he has, in conjunction with Professor Cima, made a series of experiments.

In these experiments three different classes of membranes were used: the first class comprised the skins of the frog, torpedo, and eel; the second the stomachs of the lamb, cat, and dog, and the gizzard of a fowl; the third, finally, the urinary bladders of the ox and pig.

All the experiments were made at a temperature of from 12° to 16° (from 53.6 to 59° Fahrenheit), the liquids, employed, besides pure water, were:—

	Baumé's Aerometer.	19 degrees.
Solution of sugar, of a density of ..	19	
Solution of white of egg	4	
Solution of gum arabic	6	
Alcohol	44	
These fluids were generally placed within the tube of the endosmometer, whilst the water served as immersion fluid.		

Two endosmometers were employed simul-

taneously in every experiment, the membrane in the one being placed with the internal, in the other with the external, face towards the interior of the tube. This different position of the membrane exercises a very marked influence upon the phenomenon of endosmosis.

Thus, a solution of gum arabic was observed to rise 30 millimètres in the one tube, having the external surface of the skin of the torpedo turned towards the interior of the instrument; whilst in the other tube it rose only 18 millimètres in one, and even as little as 6 millimètres in another experiment. The same marked differences were observed with a solution of sugar and of albumen: in the one tube, which had the external surface of the skin turned towards the interior of the instrument, the solution of sugar rose 30 and even 80 millimètres; whilst, in the other tube, it rose only 2 millimètres, or even remained altogether stationary. The skins of frogs and eels presented the same phenomena; the latter, however, only when fresh. When skins were used that had been detached from the animal two or three days, the several solutions were found to rise to the same height in both tubes. Eel-skin offered, moreover, another singular deviation from the general rule in this respect, viz., solution of sugar rose at first to an equal height in both tubes; subsequently, however, after the lapse of two hours, it was found to have risen 30 millimètres in the one tube, with the external surface of the skin turned towards the interior of the instrument, and only 20 millimètres in the other tube. With solution of albumen and of gum arabic the difference in the respective height of the columns of the liquids in the two tubes was observable from the beginning.

In his experiments with water and alcohol, Dutrochet found that, contrary to the general rule, the endosmotic current proceeds from the denser fluid, the water, towards the less dense fluid, the alcohol. The author's and Professor Cima's experiments in this respect proved likewise the influence of the respective position of the membrane interposed between the two liquids; with this difference, however, that the position favourable to the direction of the current from the water to the alcohol was found to differ for the three kinds of skin employed.

Thus, in using that of the frog, the current from the water to the alcohol was stronger when the internal surface of the skin was turned towards the alcohol, whilst the contrary happened when using the skin of the eel.

With regard to the skin of the torpedo, it resulted from a series of experiments, that when this skin has been recently prepared, and not been previously used for any similar purpose, the direction of the current proceeds from the water to the alcohol, the current being stronger in the proportion of three to two in the endosmometer which has the external surface of the skin turned towards the alcohol. This proportion is, however, maintained only during the first hour of the experiment: shortly after, the progressive elevation of the liquid column in the endosmometer which has the internal surface of the skin turned towards the alcohol begins to slacken; in another hour's time it comes to a stand still; and finally the endosmotic current alters its direction, and proceeds from the alcohol to the water. The elevation in the other endosmometer continues to progress steadily. The following table may serve to illustrate these several changes.

A. Endosmometer with the internal surface of the skin turned towards the water.

Elevation during the first hour	23 millimètres.
" second "	25 "
" third "	25 "
" fourth "	25 "

B. Endosmometer with the external surface of the skin turned towards the water:

Elevation during the first hour	17 millimètres.
" second "	3 "
" third "	0 "
Retropress. during the 4th "	3 "

Neither the skin of the frog nor that of the

sol offers this phenomenon of the reversion of the current, although with both of them the endosmotic process abates in intensity after the lapse of a few hours, no matter whether the inside or outside of the skin be turned towards the alcohol; this abatement follows, however, an irregular march, as the following table will show:—

A. Endosmometer with the internal surface of the skin turned towards the water.		
Elevation during the first hour	23 millimetres.	
" second "	40 "	
" third "	12 "	
" fourth "	22 "	
" fifth and sixth "	66 "	
B. Endosmometer with the external surface of the skin turned towards the water.		
Elevation during the first hour	30 millimetres.	
" second "	65 "	
" third "	15 "	
" fourth "	35 "	
" fifth and sixth "	58 "	

During the night the liquid overflowed the brim of both endosmometers.

Are the singularities which alcohol offers in this respect to be attributed to the chemical action which this fluid exercises upon the substance of the membrane, and to the consequent alteration of its structure?

Several experiments were made with a view to ascertain whether the part of the body from which the skin had been taken exercised any influence upon the phenomena: the results proved the negative.

A series of experiments were made for the purpose of determining the respective force of the endosmosis of the several liquids through the three kinds of skin. The following table shows the results—(the external surface of the skin was invariably turned towards the interior of the instrument):—

Solution of sugar	Skin of torpedo	100 millim.
	" frog	25 "
Solution of albumen	" eel	15 "
	" torpedo	30 "
Solution of gum	" frog	15 "
	" eel	8 "
Alcohol	" torpedo	120 "
	" frog	22 "
	" eel	6 "
	" torpedo	35 "
	" frog	80 "
	" eel	55 "

These results show that the order in which Dutrochet arranged the solutions of gum, sugar, and albumen, relatively to the intensity of the endosmotic current produced between them and pure water, is not the correct one in all cases—in fact, we shall see hereafter that Dutrochet's arrangement holds good only in the case of the urinary bladder (which this able experimentalist employed in his researches).

We will now proceed to the second category—viz., the results obtained with the mucous membrane of the stomach of the lamb, the dog, and the cat, and the gizzard of the fowl. The membranes used were carefully freed from all muscular fibres; in the great majority of instances, they were removed from the animals immediately after death.

To begin with the mucous membrane of the lamb. Two experiments were made with solution of sugar: in the first the solution rose 56 millimetres in the tube which had the internal surface of the membrane turned towards the interior of the instrument; in the second it rose 54 millimetres; whilst the solution in the endosmometer, where the reverse position of the membrane was adopted, rose, in the former case, 72, and in the latter 66 millimetres. These experiments lasted only one hour and a quarter. Solution of albumen, on the contrary, rose in the space of two hours 23, 28, and 35 millimetres, in the tube with the internal surface of the membrane turned towards the solution, to 11, 20, and 22 millimetres in the other endosmometer.

With solution of gum arabic the elevation was, in some instances, nil; in others, it proved equal in the two tubes, not proceeding, however, beyond 8 millimetres; in some cases the solution

rose 12 millimetres in the tube having the internal surface of the membrane turned towards the interior, to 8 millimetres in the other tube. The intensity of the endosmotic current between water and solution of gum, through the mucous membrane of the stomach of the lamb, is exceedingly feeble, and stops altogether after the lapse of a comparatively short time. It happens frequently that the solution of gum, after having, in the course of two hours, slightly risen, remains subsequently stationary, even though the experiment be continued for several hours longer.

The stomach of the cat and that of the dog differ from that of the lamb, with respect to the position of the membrane most favourable to the incitation of the endosmotic current between the solution of sugar and the water. In an experiment made with the stomach of a cat, the solution of sugar rose 30 millimetres in the tube which had the external surface of the membrane turned towards the water, to 15 millimetres in the other tube; in the case of the stomach of the dog, the elevation in the former tube was 68 millimetres, that in the latter only 8 millimetres.

The endosmotic current between the water and a solution of gum arabic through the mucous membrane of the stomach of the cat is likewise stronger when the external surface of the membrane is turned towards the water than it is in the reverse position. This applies, however, only to membranes removed immediately after the death of the animal. When using the stomach of a cat that has been dead for some time, a slight elevation is observed during the first instants of the experiment, this elevation is sometimes equal in the two tubes; at one time it is more, at another less, considerable in one and the same endosmometer; the liquids re-descend, however, very soon after. If the water be placed in the interior of the tube, and the solution of gum made to serve as immersion fluid, the former liquid descends. The stomach of the dog offers the same phenomena in this respect.

Several experiments were made with the stomach of the dog, removed several hours after the death of the animal; solution of albumen was employed in these experiments. The solution rose to an equal height in both tubes, in four different experiments: in one experiment, which may serve as a general type of the others, the solution rose 20 millimetres in both tubes in the space of one hour; it remained subsequently for three hours stationary in the tube which had the external surface of the stomach in contact with the water; whilst, in the other tube, a retrogression of 25 millimetres occurred in the same space of time. Generally speaking, the liquid column remains seldom stationary in either of the two tubes. In the great majority of cases the liquid re-descends in both tubes after attaining a greater or less height; but the decrease in the tube having the external surface turned towards the solution of albumen is double, and frequently even treble, that observed in the other tube. If the position of the liquid is reversed (the water being placed within the tube, and the solution of albumen without) the internal liquid descends equally in both tubes. The retrogression of the internal liquid, observed in the experiments, is owing simply to the cessation of the endosmotic process, in consequence of alteration in the structure of the membrane supervening some time after death; but the influence of the respective position of the two sides persists, to a certain extent, even in the altered membrane.

With the mucous membrane of the gizzard of the fowl the endosmotic current between water and solution of sugar proceeds more strongly from the external to the internal surface of the membrane, although the difference in the respective elevation of the liquid in the two tubes is generally inconsiderable—such as, for instance, 48 millimetres to 13. In some experiments, however, the solution of sugar was observed to rise 17 millimetres, 20 millimetres, &c., in the one tube, which had the external surface of the membrane directed towards the water, whilst it remained perfectly stationary in the other tube.

It is, moreover, worthy of remark, that the endosmotic current from the water to the solution of sugar, through the mucous membrane of the gizzard of a fowl, continues invariably only for a very limited period; in general, the liquid column becomes stationary in both tubes after the lapse of two hours at the most.

The endosmosis between water and solution of albumen, through this membrane, seems to proceed equally in both tubes. Amidst a number of experiments, only one single instance was observed in which the albuminous solution rose 15 millimetres in the tube having the external surface of the membrane turned towards the water, to 5 millimetres in the other tube.

The same applies to solution of gum—the elevation is almost invariably equal in both tubes. In the few exceptional cases, where a trifling difference of one or two millimetres was observed in the relative height of the liquid in the two tubes, this difference was invariably in favour of the tube that had the internal surface of the membrane turned towards the solution of gum.

When employing alcohol as internal fluid, and the mucous membrane of the stomach of the lamb, cat, and dog, as interposing medium, the endosmotic current proceeds invariably from the water to the alcohol, and is most active in the direction of from the internal to the external surface of the membrane.

When employing the mucous membrane of the gizzard of a fowl as interposing medium, the endosmotic current proceeds, contrary to the general rule, from the alcohol to the water, and is strongest in the direction of from the internal to the external surface of the membrane.

We will now proceed to the consideration of the results obtained when employing the mucous membrane of the urinary bladder of the ox as interposing medium. The membranes used were fresh, and had been carefully freed from all muscular fibres. Solution of sugar rose 80, and even as many as 113 millimetres, in the usual space of two hours, in the tube having the external surface of the membrane turned towards the water, to 63 or 72 millimetres in the other tube; which shows that the endosmotic current from the water to the solution of sugar is strongest in the direction of from the external to the internal surface of the membrane. The reverse was observed with solution of gum arabic; this solution rose 18, and sometimes even only 7, millimetres, in the tube that had the external surface of the membrane turned towards the water, whilst it rose from 20 to 52 millimetres in the other tube. In some cases, however, the solution of gum arabic was at first observed to descend in both tubes, and subsequently, after the lapse of some time, to rise in the same respective proportion as solution of sugar presents. In one experiment the liquid retroceded in both tubes to the extent of 7 millimetres in the space of one hour; it began subsequently to re-ascend, and three hours after, it had risen 12 millimetres in the tube that had the external surface of the membrane in contact with the water, and 8 millimetres in the other tube.

No endosmosis takes place between water and solution of albumen when the mucous membrane of the urinary bladder of the ox (in a state of freshness) is employed as medium of interposition; the liquid descends in both tubes, no matter whether the albuminous solution be used as internal fluid, or as immersion fluid. It should, however, be observed here, that the decrease of the column is less considerable when the internal surface of the membrane is in contact with the solution of albumen placed outside the tube as immersion fluid, than when the membrane is placed in the reverse position; and that the contrary happens when this solution is inside the tube, and in contact with the external surface of the membrane.

Finally, with regard to alcohol and gum-water, the endosmotic current proceeds from the latter to the former; in one experiment the alcohol rose 24 millimetres; in another 59 millimetres, in the tube having the internal surface of

the membrane in contact with the water, to 26 and 17 millimetres in the other tube.

These marked differences, which are observed when using fresh membranes, disappear quickly, or nearly so, when dried bladders are used. Bladders that have been altered by an almost adjoined putrefaction. The results of the few experiments made in this respect with dried bladders of the ox or pig (that had previously been moistened, to render them fit for use), have shown that the elevation of the liquid is equal in the two tubes, whatever be the position of the membrane, and that if any trifling difference occur, this is altogether independent of the respective position of the latter. When the same bladders are used, after having been kept in water for several hours, the effects are sometimes found in a certain measure analogous to those obtained with fresh bladders, but if the bladders used have been kept in water for a whole night, no elevation is observed in either tube, or the elevation is equal in both. We can in a certain measure account for these anomalies when a dried bladder is kept long in water, the muscular fasciculi swell, acquiring thus great thickness and approaching close together, so that, returning to its state analogous to that of freshness. Now, several experiments have proved that the muscular membranes of the gizzards, and stomachs will not permit the process of endosmosis if they are not previously freed from muscular fibres. In bladders that have been exposed for a shorter time to the action of water, the muscular fasciculi are indeed slightly dilated, but not so much as to leave interstices between them, through which endosmosis may be effected. But the inequality of the interstices, the two symmetrical positions of one and the same bladder, must necessarily cause vague and uncertain results.

Some experiments made with gizzards of fowls in a state of more or less advanced decomposition (with a view to ascertain the influence of putrefaction on the phenomena of endosmosis) gave very contradictory results. In some instances the liquid failed altogether to pass through the membrane, in others it attained to an equal elevation in the two tubes. In some cases the endosmosis was energetic, at one time in one sense, at another in another sense, and thus altogether irrespective of the nature of the liquid used and of the disposition of the membrane. In some cases, the liquid descended in both tubes. In treating elsewhere of the results obtained when a living skin or the mucous membrane of the stomach of certain animals we had occasion to remark how much the phenomena of endosmosis differ according to the membranes are used, and finally upon the death of the animal, and after. All these facts show clearly the intimate relation that exists between the phenomena of endosmosis and the physical condition of the membranes.

The phenomena of endosmosis, like all others that manifest themselves in organized tissues, does not present this as an any and every, which we observe in the physical phenomena of the inorganic world. First, these variable and accidental conditions in the membranes that are to be attributed to the observed differences, in the respective elevations of the fluid, which we see, for instance, at a time rise to 80 millimetres, and at another to 10 millimetres, though the liquid and membrane are in the respective position of the latter in both cases. The difference of elevation which invariably attends the difference in the respective position of the faces of the membrane, in the same membrane, be referred to a constant difference in the physical condition of the latter, and not to any difference in its functions. It would be important to determine the influence of certain accidental conditions (such as the deprivation of food, the death of a certain animal, the killing it &c.) upon the phenomena of endosmosis through fresh membranes. The author has made one comparative experiment only in this respect,

of which the results have led him to conclude that the endosmosis through the skin of the cell is more energetic when the animal has been kept several days out of water.

A careful comparison of the results obtained in the preceding experiment on the various membranes leads to the deduction of the following general conclusions.

1. The membrane interposed between the two liquids performs a very active part, both with regard to the intensity and to the direction of the endosmotic current.

2. In general, every membrane affects a certain position of its two faces (relatively to the two liquids), in which the endosmosis proceeds with greater intensity than in the reverse position, the exceptions from this rule are very few, as far as fresh membranes are concerned.

3. With regard to skins, the direction most favourable to the endosmotic current is generally from the internal to the external surface, with the exception of the skin of the frog in the endosmosis between water and alcohol, when the current is most strongly incited in the direction of from the external to the internal face.

4. With the mucous membranes of the stomach, and those of the urinary bladder in animals, the direction most favourable to endosmosis varies according to the different liquids, most variable is the case with skin.

5. The phenomenon of endosmosis is closely and intimately connected with the physical condition of the membranes.

Dried membranes, or such as have been altered by putrefaction, either fail altogether to produce endosmosis, or do not present the usual difference in the intensity of the endosmotic current according to the respective positions of the faces of the membranes.

To account still only for the results of the experiment on endosmosis, and the conclusions deduced from them, it is indispensable that we should consider how in every point of view different from that in which it has hitherto been looked upon, the augmentation of volume presented by the internal liquid, which is usually the denser of the two, is regarded by Dutrochet as a result of the difference between the strength of attraction, and the feeble current.

According to this view, the one of the two liquids which has come from its antagonistic fluid more than yields to it, should augment in density proportion to the excess of the gain over the loss, or in other terms, to the difference between the strong and the feeble current. The adoption of this view would compel us to admit that all the facts observed in the numerous experiments on endosmosis lead to the conclusion that the various membranes allow the water to pass through liquid in the endosmometer more readily according to the respective disposition of their surfaces, and likewise according to the nature of the internal fluid. But this mode of viewing and explaining the phenomena of endosmosis presents a great many difficulties which need not be further particularized here, as they are so obvious that they will necessarily have occurred already to the reader of this treatise. It will, therefore, suffice to remark that, in attributing everything to endosmosis, the presence of the solution of gum or of sugar in the interior of the endosmometer will not afford us the slightest explanation of the phenomena presented by the internal membrane of the stomach of the lamb and the mucous membrane of the urinary bladder of the ox. These phenomena are susceptible of a more easy and natural explanation. We admit that the divers membranes placed in contact with fluids, by exosmosis, a portion of the water, more or less readily, and with the solids are in contact with the water, the force of their respective forces opposing always the endosmotic current to produce the water to the denser liquid, according to the usual general law of endosmosis.

This view has been submitted to the test of experiments by the author and Professor Cima. The skins of the frog and cell were used in

these researches, salt water in all, in some cases, solution of sugar were employed as denser (or internal) liquid. The endosmometers were prepared as usually, the skin being placed, in the one with the internal, in the other with the external surface turned towards the interior of the instrument. Equal volumes of salt water of known density were introduced into both endosmometers, which were then placed in separate vessels of crystal, containing each a volume of distilled water equal to that of the salt water in the tube. After the lapse of a few hours, the volumes of the liquids, both in the tubes and the vessels, were accurately measured. The result proved that the endosmotic current from the water to the salt water had proceeded with greater intensity in the direction of from the internal to the external surface of the skin, than in the opposite direction. In determining the respective density of the liquids in the two tubes, and of the water in the two vessels, it was found that in the endosmometer in which the volume of the salt water had increased most, the density of the solution had been preserved in contact with the water, and, *vice versa*, that the amount of saline solution introduced by exosmosis was smaller in the vessel which had lost the greatest amount of distilled water, than in the other vessel.

The subjoined table gives the numeric results of the endosmosis experiments that have been selected from amongst eight hundred. The first column indicates in tenths of cubic centimetres, the respective volumes of the liquids found in the tubes after the experiment, the second volume shows the weight of a given volume of these liquids, the third how the respective volumes had stood in water and in the two vessels after the experiment, and the fourth column indicates the accession of water during the experiment to a given volume of water in the vessels. The respective weight of equal volume of salt water and distilled water, before the experiment, was 17.00 grammes of the former and 16.00 of the latter.

FROG'S SKIN.			
I.	II.	III.	IV.
1000	17.00	5.21 mm.	112.0
1100	17.80	"	115.0
LAMB'S SKIN.			
1000	17.10	"	200.0
1700	17.10	"	0.0

In some cases the experimentalist precipitated with nitrate of silver the salt contained in the two external vessels. The last column of the subjoined table shows the result.

FROG'S SKIN.			
I.	II.	III.	IV.
1720	17.10	21 mm.	160.0
1710	17.17	"	161.0

Similar results were obtained with solution of sugar, as the following table will show. 18.180 grammes was the weight of a given volume of the solution of sugar before the experiment.

LAMB'S SKIN.			
I.	II.	III.	IV.
1000	18.03	31 mm.	181.0
1010	18.010	"	193.0

These facts are inexplicable upon the supposition that the elevation and increase of volume of the liquid in the two tubes are simply the result of the difference between the current of endosmosis and that of exosmosis. If this were really the case, the endosmometer in which the volume of the salt water has increased most ought to contain a less dense liquid than the other in which the volume has increased least. But these facts may be at once satisfactorily explained upon the assumption that the endosmotic current is equal, or nearly equal, in both positions of the membrane, and that the reason of the difference lies simply and entirely in the current of exosmosis, which is less intense in the endosmometer in which the elevation is most considerable, and more energetic in that in which the elevation is less.

These results give great importance to the action of the membrane interposed between the liquids, indeed, the peculiar nature and physiological function of the membrane enable us to account for the more or less ready passage which

it affords to divers liquids of greater density to wards a fluid of less density.

The important subject of endosmose, as effected through the divers fresh membranes, demands still a very attentive study, and requires many more experiments and researches, particularly with regard to comparison between the stomachs of different species of animals, and more especially between the stomachs of the carnivorous and herbivorous animals. This much, however, the author ventures to assert, that his experiments and his notion of exosmose conduce to a more correct application of the phenomena of endosmose to the functions of organized bodies.

The exosmose of solution of sugar, albumen, and gum, through the divers skins examined by the author, is most energetic in the direction of from the internal to the external surface, and it is precisely in this same direction that an abundant secretion of mucus proceeds through the skin of the torpido, eel, frog, and other animals. The endosmotic current from the water to the solution of sugar, albumen, and gum, is less intense from the external to the internal surface of the skin; than in the reverse direction. Consequently, even if it be not admitted that it is entirely to the phenomena discovered by the author and Professor Lima that are owing this direction of the mucous secretion and the feeble absorption of the water in which these animals exist—functions which must necessarily stand in a certain relation to another, to permit their normal exercise—it cannot be denied, at all events, that these phenomena exercise a considerable stimulative influence upon those functions. This much seems certain, that the skin of those animals, which live constantly in the water could not perform these functions, or, at all events, could not perform them well, if the endosmotic action of this membrane proceeded in a direction the reverse of that in which the author's experiments have proved it to proceed.

We disregard here, of course, the anomalous phenomena observed with water and alcohol, when the skin of the frog is used as medium of interposition; alcohol has no correspondent amongst the fluids found in the animal organism; and, if the anomalies that have been observed when using it as endosmotic liquid should be confirmed with regard to the human skin, they would find their application rather in therapeutics than in physiology.

The mucous membrane of the stomach of the different animals does not present this constancy, as regards the direction in which the endosmotic and exosmotic currents proceed with the greatest vigour. But every one knows how much more complicated are the functions of the stomach than those of the skin, and that this organ does not absorb all the substances introduced into it, or absorbs them but very unequally. The fact that the stronger current from the water to a solution of sugar, for instance, follows a different direction through the mucous membrane of the stomach of a ruminant than through that of the stomach of a carnivorous animal, shows clearly that the phenomenon of endosmose is intimately connected with those essential modifications to which the digestive functions are respectively subjected in those two orders of animals.

The great importance of endosmose in the functions of life has induced us to give in detail the results of the experiments made on this subject. It is by endosmose that physiologists now account for the nutrition of the ovules in the ovaries of the mammiferous animals; and explain how it happens that the vesicles containing the sperm of the cephalopodous (or spermatophorous) mollusca open immediately upon coming into contact with water.

Before concluding this subject, we have to mention certain experiments made by Poiseuille, with a view to account by endosmosis for the urgative action of certain substances. The experimentalist observed that the endosmotic current through the animal tissues proceeds from serum to seidlitz water, and to the solutions of sulphate of soda and of sea salt; and this is

precisely what happens when these substances are used internally. The excrements contain an abundant and unusual quantity of albumen. It must be admitted here that endosmose takes place from the serum of the blood to the saline solution, through the capillary vessels of the intestine.

But, to place the correctness of Poiseuille's conclusion beyond doubt, it was indispensable to demonstrate that endosmose still takes place, even though one of the liquids be in a state of motion and incessant process of renewal. This desideratum has been supplied lately by Dr. Baccchetti, who has proved by experiments that the energy and velocity of the endosmotic process are considerably increased when one of the two liquids is incessantly being renewed. This result is, moreover, perfectly in accordance with the principles of the theory of endosmose: the constantly proceeding interchange of the liquids through the membrane tends certainly to suspend the action of endosmose; or, in other terms, the conditions for the manifestation of the phenomenon are preserved the more intact the longer the fluids continue without intermixing. Poiseuille has likewise shown that membranes, after a certain time of action, lose their endosmotic faculty with respect to the liquids with which they happen to be in contact, but that this faculty may be restored to them by making them act for some time upon other fluids.

The most remarkable fact of those discovered by Poiseuille, on the subject of endosmose, is that the influence which hydrochlorate of morphia exercises upon this phenomenon. The addition of this substance to saline solutions considerably suspends the endosmose from the serum to the solution, and changes finally the direction of the current. Dr. Baccchetti has confirmed this fact, which is of a nature to aid the physiologist and physician most materially in their endeavours to explain the remedial action of morphia and their preparations of opium in cases of diarrhoea, and the constipation resulting from the administration of these agents.

ACADEMY OF SCIENCES.

Meeting of June 21; M. BRONGNIART in the Chair.

COMPOSITION OF THE BLOOD IN SCURVY. BY DRS. PELLETIER AND RODIERE.

An interesting monon on this subject was presented by the authors to the academy. The following is an abstract.

Scurvy, more common and more fatal during the middle ages than at present, has always been attributed to an alteration of the blood. Boerhaave and Hoffman considered this alteration to consist in a sort of dissolution of its solid particles, Lind held a similar opinion; Haygarth attributed the disease to the alkaline condition of the circulating fluid. Modern researches have led to somewhat more precise results, and that state which was formerly called "dissolution" in the blood may be translated in the language of modern organic chemistry by the words "diminution of fibrin," or "de-fibrination." Thus, ingenious experiments of M. Magendie tend to show that a scorbutic state of the blood must be referred to a decrease of its fibrin, and to an augmentation of the quantity of alkaline salts naturally contained in that fluid. Messrs. Andral and Gavarret having twice abstracted blood from a patient affected with scorbutus, and having on each occasion found a diminution of the average quantity of fibrin, attribute the disorder to this primary modification. These researches not being sufficiently numerous to settle in a definitive manner the pathogenic problem connected with the question, the authors embraced the opportunity offered by an epidemic scurvy, which showed itself during the spring of the year 1846, to examine further into the subject, and, by care-

fully analysing the blood, to remove, as far as possible, the darkness with which it is still surrounded.

Five of the patients affected were in a condition which warranted venesection, and these five cases, the principal features of which are detailed in the memoir, present with each other the closest analogy. All were aged females, and had resided at least six months in the asylum; all the disease manifested itself in the usual manner, viz., general debility, frequent epistaxis, swelling of the gums, petechial patches on the legs, occasional pains in the extremities, &c. The scorbutic stains were also the seat of considerable tenderness on pressure, and the pulse was small, weak, and depressible. In connection with the results of chemical analysis of the blood in these five cases, the authors remark that, although the globules had fallen below their average standard, in no instance was a sufficient quantity present in the arteries or in the heart. It should be recollected, however, that it is only when the quantity of globulin descends below 10 in 1000 parts of blood that bellows murmurs are almost invariably found in the carotid arteries—a circumstance which could have been served in one case only. We now proceed to state the exact composition of the blood in each of these five cases:—

					Av.
Urine	...	2.6	3	12	6.8
Organic matter of serum	...	6.31	1.2	6	3.1
Organic matter of blood
Alkaline soluble salts	...	7.3
Alkaline insoluble salts	...	8.11	5

The density of the blood was found to be 1.047-2, 1.051-7, 1.048-6, 1.050-6, and 1.038-3—mean d., 1.047-3.

The authors conclude, from their researches—That the analysis of the blood in these five instances of scurvy did not show any of the characters of dissolution described by ancient writers, and hitherto admitted without discussion; neither has the alkaline quality of the blood appeared to have been increased. 2. That the blood was clearly deprived of a portion of its usual amount of globules—a circumstance which must not be looked upon as the cause of the disease, but as a result of loss of appetite by which it was constantly attended. 3. The quantity of urine was natural, and even perhaps slightly increased. 4. The only positive alteration which was possible to detect in the blood was a very considerable diminution of its specific gravity—a diminution not by any means in proportion with the decrease of the solid components of the circulating fluid.

ETHEREAL VAPOUR.

M. Pirogoff, of St. Petersburg, forwarded to the institute a volume containing the result of his experience on the subject. The work was accompanied by a letter, in which the author mentioned that he had occasion to employ injections of ethereal vapours in the following cases:—Twice in the partial removal of the upper jaw, three times in the operation for artificial pupil, and twice for strabismus; once in rhinoplasty, once in the removal of two metacarpal bones, and once in lithotomy. In none of these cases was ethereal insensibility followed by any unpleasant consequences, and in the operations performed on the eyes the author states that the perfect immobility of the eyeball greatly facilitated the surgical process.

The success obtained by M. Pirogoff in the application of his method having reached the ears of the Emperor of Russia, his Majesty has sent M. Pirogoff to the Caucasian army, in order that the benefit of ethereal injections may be extended to those who undergo operations in consequence of wounds inflicted on the field of battle.

ACADEMY OF MEDICINE.

Meeting of June 22; M. BROWN in the Chair.

LITHOTRIPSY AND LITHOTOMY.

M. Civide read a report on a paper by M.

Chauvette, of Bordeaux, on the relative advantages of these two methods of treatment of calculus. The reporter, adopting lithotripsy as a general method for the removal of the stone in children, was of opinion that cystotomy should be resorted to when the concretions were voluminous, and might require, therefore, several operations in order to be crushed with complete success. M. Chauvette had twice vainly endeavoured to apply ethereal inhalations to lithotomy; but cases were not yet sufficiently numerous to warrant any conclusive remarks on the subject. M. Civiale did not think that vesical catarrh was more frequently observed as a consequence of lithotripsy than of lithotomy, but a reappearance of the concretions was more common after the latter than after the former operation. Foreign bodies introduced through the urethra into the bladder were generally looked upon as requiring the operation of cystotomy; still M. Chauvette had, with the assistance of lithotriptic instruments, succeeded in extracting from the vesica various foreign bodies—such as peas, beans, two bougies, one pencil, and a barometer-tube. The reporter proposed the thanks of the academy to the author, and the publication of his paper.

M. Roux requested permission to make some observations on the report. M. Civiale did not seem partial to the use of ethereal inhalations in cases of lithotomy; now, M. Roux had lately performed the operation twice during insensibility produced by ether, and begged to lay the cases before the meeting. The first was that of a young man, aged twenty-one, from whom a calculus of oxalate of lime was extracted after a long and difficult operation. Insensibility had been induced previously by the inhalation of ether, and the patient declared that he had experienced no pain. The operation was performed on the 9th instant, and the case was progressing most favourably in every respect, and deserved attention, inasmuch as it might justify the inquiry as to whether, with the assistance of ether, lithotomy might not in all cases be considered preferable to the method of crushing the stone in the bladder. The second operation had been performed eight days ago, on a man aged eighty-two. This man had undergone lithotomy on three different occasions—sixteen years ago by M. Civiale, and since then by M. Légalas and by M. Menier; altogether, this process had been instituted in the present case at least one hundred times, each operation requiring a great many attempts before arriving at its full completion. On removing the calculus a week since, M. Roux had also extracted a large caoutchouc catheter, which, from its appearance, had undoubtedly been a long time deposited in the bladder. The man did not recollect anything whatever about this catheter, and could give no information as to the period or manner of its introduction. Previously to performing cystotomy, M. Roux had caused the patient to become unconscious by the inhalation of ether, and no pain whatever attended the operation, which had, it was true, been followed with symptoms of nervous prostration, refractory, perhaps, in some degree to the ether.

M. Civiale perfectly recollected the patient but could not give any information with regard to the bougie found in the bladder.

M. Blandin would not give an absolute opinion as to the advantages to be derived from ethereal inhalations in lithotomy. As to the innocuity of lithotriptic operations, asserted by M. Civiale, M. Blandin could not admit it. The occasionally severe consequences of the simple introduction of bougies protested loudly against M. Civiale's opinion; and its besides he already, on various occasions, shown that it attempts to crush the stone sometimes brought on most unpleasant and even dangerous results. M. Civiale, speaking of relapses, said that the reappearance of calculi in the bladder was more commonly observed after cystotomy than after lithotomy: how could this be, if, as it was admitted on all hands, relapses were the consequence of a diathetic predisposition of the sub-

ject? M. Civiale had also said that vesical catarrh was more frequent after lithotomy than after the other mode of operation. M. Blandin held that the contrary assertion was more true. Was it possible to believe that the bladder was less irritated by lithotriptic manœuvres than by the incision of lithotomy? M. Civiale was obliged to acknowledge the existence of unsuccessful cases of crushing, and attributed them to the novelty of the method; but it had now thirty years' existence, and that argument must, of necessity, fall to the ground.

The conditions of the report were then adopted.

SPARKLING SYNCHISIS.

Dr. Desmanes presented to the academy two patients affected with this variety of ocular disease. In one the bright specks were innumerable; but in the other they obeyed the laws of specific gravity, and were thrown into agitation by every movement of the eyeball. (See *Medical Times*, vol. 13, p. 283.) It may be recollected that three opinions have been brought forward for the explanation of this singular phenomenon: M. Malgaigne conceives that particles of cholesteroline floating in the eye may cause it; M. Siegel attributes the appearance to the presence of the vitreous humour of minute shreds of the hyaloid membrane in a state of disorganization; and M. Desmanes believes that it is an optical delusion of the observer, produced by the relaxed condition of the hyaloid cells in the diseased eye, in consequence of which these cells reflect rays of light that they are destined to refract.

The meeting adjourned at five p.m.

MIDWIFERY.—STATISTICS OF THE LYING-IN HOSPITAL AT WITZSLBURG. BY PROFESSOR HOLTMANN.

From January 1, 1812, to October 31, 1815, 637 accouchements were observed—31 cases of twins, and one "mole." Of these 651 children, 49 were stillborn.

D. McCARTHY, D.M.P.

Wounds from Firearms without Ball.—The *Philadelphia Medical Examiner* records a case, communicated by Dr. Paul Swift, of a young man who was shot by a pistol charged with powder only, by which a fatal wound was inflicted. It was on the fleshy part of the left hip, above and behind the trochanter major, about one inch in diameter, and four inches in depth; the integuments were destroyed, and the muscles presented a blackened, mangled mass: it bled but little, and was carefully probed with the finger, which readily passed to the bottom of the wound. No untoward symptom arose till the sixth day, when tetanus in its most distressing form supervened, and on the following morning he died. The wound was at least four times as large as a ball from the same instrument would have caused; and so mangled were the tissues, through this great extent, that vitality was utterly destroyed. It is not certain at what distance the pistol was held when the wound was inflicted, the patient supposing that it nearly touched him, while the witnesses varied in their statements at the trial from one foot to two or three yards. There was no wad either found or supposed to be used.

Experiments in Reference to Gunshot Wounds inflicted without Shot.—The pistol used had a bore four inches in depth, and six lines in calibre, and was wadded with paper. The dead subject upon whom the experiments were tried was a male, thirty-five years of age, not recent, and had undergone a preserving process with chloride of mercury, considerably hardening the muscles; it was also much emaciated. In the first experiment the pistol, with an ordinary charge, was held twelve inches from the fleshy part of the hip, the part being covered with one thickness of broad cloth and a twilled cotton cloth under it. Clothes lacerated, and skin abraded; wad on the floor

on fire.—Experiment 2. Distance six inches; parts covered as before. Clothes lacerated; wad lodged one half inch below the surface.—Experiment 3. Distance two inches. Wound ragged, blackened with powder, and penetrating to the bone. One and a half to two inches; wad was found immediately beneath the integuments, and somewhat on one side of the principal wound; parts covered as before.—Experiment 4. Distance one inch and a half from the ribs of the right side; no covering of cloth. Penetrated the cavity of the chest, the wad passing through the intercostals between the ribs.—Experiment 5. Distance the same; no covering of cloth. The integuments removed; wad penetrated the thorax, carrying away a transverse portion of the rib.

Polypus of the Rectum.—The patient was a child, delicate from her birth, and when three years old, her mother observed that she suffered much distress previous to the act of defecation, and before it could be accomplished there was a protrusion of a dark red fleshy substance *ex ano*, which bled less or more on every occasion of the kind. The tumour was shortly associated with a second of a smaller size, which, after remaining some months, separated from the larger one; this latter continued to enlarge until it had acquired the size of a small hen's egg. It was very troublesome, requiring to be placed within the sphincter and after every evacuation. This prolapse of the polypus always took place before the evacuation of the intestine, and never went up without manual assistance. This continued up to the age of five years, when Dr. Robert Burns, of Frankford, Pennsylvania, was consulted. The polypus was then found as large as a small Seckel pear, being considerably diminished at the time from frequent bleedings. On dilating the anus, the pedicle was found to be somewhat elongated from the mucous membrane of the rectum above the sphincter; to this was applied a ligature of silk immediately, allowing the ends to remain long, which were secured externally by a strip of adhesive plaster; about twenty-four hours after its application the polypus separated, and two days after the ligature came away. She suffered some pain while it remained. Since its removal no unfavourable symptom has occurred, and the functions of the part are quite natural.

The Treatment of Miasmatic Fever.—Dr. G. L. Upshur, of Norfolk, Virginia, had during the past year 105 cases of this fever under his superintendence. Of these eighty-three were intermittent, and twenty-two remittent. Of the intermittent, one was quartan, fifteen tertian, sixty-two quotidian, and five masked. Of the masked, one took the form of neuralgia, and four simulated hysteria. The treatment chiefly employed was the sulphate of quinine in large doses, without regard to the stage of the disease. In one case, a quotidian, occurring in a youth aged 16, of excitable temperament, fifteen grains were administered just as the cold stage was passing off. All the symptoms were ameliorated; the hot stage lasted but one hour, and the patient had no return of the disease. In twenty-five cases, thirty grains were given in five hours, during the height of the febrile stage. The pulse was lessened in force and frequency in every instance, and the paroxysm cut short by the speedy appearance of perspiration. In only one of these cases was the remedy preceded by other treatment. Dr. Upshur, from his experience, deduces the following conclusions:—1. In a large majority of cases, no matter of what type the fever is, the preparatory treatment, so called, is worse than useless, causing a loss of time which is often fatal to the patient. 2. A large dose of quinine (fifteen or twenty grains), administered at once, produces a more certain and permanent curative impression upon the system than small doses (one or two grains) frequently repeated. 3. Quinine in large doses, when administered in the hot stage, so far from exciting the circulation acts as a decided sedative upon it, the pulse in every instance lessening in force and frequency under its influence. The dogma, therefore, that quinine in fever is poison, must be discarded.

4. In uncomplicated malarial fever, mercurials are not at all essential to a complete and permanent cure. They may be sometimes given with advantage in cases where cathartics are indicated at the onset of the disease.

Polypus Uteri.—Dr. Wood exhibited to the New York Pathological Society a specimen which had existed for nine years, and which he removed by ligature. It was about the size of a Vergaloo pear, and hung by a well-defined pedicle from the fundus. Several fibrous tumours were attached to other parts of the uterus, appreciable by the hand externally applied, varying in size from that of a marble to that of a fist. In three days after the application of the ligature the polypus came away without hemorrhage; it had nearly lost half of its bulk. It was supplied by one large artery in the pedicle, which gave off other small ones. It was difficult to secure arteries after their section on all fibrous tissues, as soon, owing to their elasticity, is not given for the hold of the ligature beyond the tenaculum. Hence the great danger of excising these growths, which Dr. Wood considers a bad and hazardous practice.

Aneurism of the Femoral Artery, and Communication of the Artery and Vein.—A gentleman, aged twenty-one, had been wounded two years and a half before his death in an affray, with a pistol-ball, which entered below the ant. sup. spinous process of the ilium, traversed the front of the thigh, and came out on the inside of the symphysis, under the skin. At the moment much hemorrhage ensued, arrested by pressure. He recovered entirely in six weeks; but on getting about discovered a pulsating tumour in the middle of the thigh, three inches below Poupart's ligament. When examined, it was irregular and ill defined; three or four inches in circumference, and over it, a very unusually distinct thrill could be felt. The tumour was in contact with Poupart's ligament. The external iliac artery was tied by Professor Mott, on the 16th of December, and on the 22nd he died, gangrene having extended over the whole limb, commencing at the foot. At the post-mortem examination, a little lymph upon the peritoneum around the wound was discovered. The ligature was applied about one inch and a quarter above the circumflex and epigastric arteries, and a clot of about an inch in length was above it. The artery began to be atheromatous just below Poupart's ligament. A true aneurism communicated with the artery just above the origin of the arteria profunda, a little larger in size than a partridge's egg, and of a regular oval shape, like a pouch, having a small jug-like neck, and containing coagula formed before the ligature of the artery. It was enveloped by gristly cellular tissue. Immediately under the sac, and blended with it, was the anterior crural nerve much larger than natural in appearance, from thickening, probably, of its cellular neurilemma. The vein along the side was healthy, but thickened, and the cellular tissue at this point infiltrated and indurated. Just here existed a communication between the vein and artery. A little cyst of bony shell was attached to the surface of the vein just where the saphena dips into it. Dr. Van Buren, who relates the case, believes it to be unique; an aneurismal varix, and a true aneurism of the femoral artery.

Artificially-shortened Funis, with Rupture before Delivery.—Dr. Wilson Jewell read before the Northern Medical Association of Philadelphia a case of this kind. It occurred to a lady in labour with her fifth child. Her previous deliveries had always been remarkably quick when now visited she had strong pains, and the child's head was pressing forcibly during pain against the perineum. As the pain subsided the head receded quite high up, and remained there till the following pain brought it down. For two hours this state of things continued, when powerful and continued effort of the womb expelled the head of the child beyond the vulva; yet when action ceased the head remained firmly wedged against the os externum. The appearance of the child at this stage of the birth indicated strangulation, without speedy relief, and it

was now discovered, by passing the finger round the neck, that it was closely compressed, by being encircled with two turns of the cord, which was thus artificially shortened. At the next pain the cord suddenly gave way, and at the same instant the child was precipitated into the world. The rupture took place about two inches from the navel, and in a few minutes the child breathed and cried freely. Dr. Jewell considers this case of spontaneous rupture of the umbilicus, so novel in its character, as to be the only instance on record.

Retention of Urine, a Sequela of Scarlatina, successfully treated with Stychnia.—A delicate child, seven years of age, of strumous diathesis, was attacked with scarlet fever, and attended by Dr. Upshur, and the case progressed towards recovery, under the use of calomel and ipecacuanha, with an occasional dose of castor-oil and an emetic. Shortly after the patient had ceased taking medicine he complained of pain about the neck of the bladder, and inability to make water. When Dr. Upshur saw him again there were feverishness, headache, and a distended bladder. He was immediately put into a warm bath, and a dose of castor-oil with forty drops of laudanum given. This failing to produce relief, the next morning the catheter was passed with some difficulty from the smallness of the parts, and the existence of a partial congenital phymosis. Three congenital strictures were passed, and not more than eight ounces of urine drawn off, from the catheter becoming clogged with mucus. Next day no urine had passed, when a warm bath was ordered, tobacco-leaf steeped in alcohol applied to the perineum, nauseating doses of tartar emetic given, and, finally, an opiate enema. These failed to relieve, when the catheter was again passed, and a quart of urine drawn off, with entire relief. The retention continued, and two days after, in attempting to introduce the catheter, coming in contact with a structure, it was retained there for nearly ten minutes, when the spasm suddenly gave way and a stream of urine forcibly ejected the instrument from the urethra, and half a pint of water was passed. He was then ordered the following pills:—*R.* Stychnia, gr. ss.; pulv. rhen, gr. xx.; m. pil. 8. Take one every five hours. Four pills were taken during the night, and half a pint of urine discharged. From this time he continued to pass his urine with greater freedom, and the pills were discontinued the next day on account of the spasm of the muscles.

The Effects of Large Doses of Sulphate of Quinine.—Dr. W. F. Thom mentions four cases in which he administered large doses of this drug, in intermittent fever. He noticed that, while the patients were under the influence of the quinine, they had weak tremulous pulses and torpidity of intellect, which, however, speedily subsided. The phenomena he considers as only explicable on the idea that quinine exerts a powerfully sedative action on the nervous system. The symptoms manifested, though in a less degree, were not unlike those exhibited by some constitutions under the peculiar action of mercury, and described by Mr. Pearson as mercurial cretinism.

Affection of Peyer's Glands in Adynamic Fever.—Dr. Swett stated, at a recent meeting of the New York Medical and Surgical Society, that he had lately three cases of typhus throwing some light on the pathology of the disease, especially as to the condition of Peyer's glands. In the first patient no alterations were discovered, but some patches of the gland, near the ileo-cæcal valve, were enlarged and discoloured, being of a reddish-brown hue. In the second, a girl of twenty, who had the ordinary symptoms, the glands of Peyer were much inflamed and ulcerated. The third case was that of a boy, who had suffered much privation at sea, and was attacked a week after landing. When seen by his medical attendant he was exceedingly prostrate. Stimuli were given with temporary benefit; but he lived only a fortnight. A day or two before his death, livid discolorations, of a

linear form, appeared about the abdomen, as if from the bursting of veins. No disease of Peyer's glands was discovered, on a post-mortem examination, except that some of them were hypertrophied—the results of former disease. In the cæcum there were about a dozen sloughing ulcers, irregular in shape, the largest of them about the size of a threepenny-piece. Taking the three cases, it appears the disease, though of common origin, may or may not be attended with ulceration of Peyer's glands.

Ulcer of the Stomach.—Dr. George Budd remarks that Rokitsanski, who has studied the morbid anatomy of the disease with his accustomed patience, states that of seventy-nine cases, of which he has given an analysis, the ulcer was situated—

- In 15, on the lesser curvature.
- 20, on the posterior wall of the stomach.
- 16, at a small distance from the pylorus.
- 16, in different parts at once; especially simultaneously on the anterior and posterior surfaces.
- 1, at the fundus of the stomach.
- 6, in the duodenum.

79
This disease is met with more frequently in women than in men. In the seventy-nine cases, forty-six occurred in women, thirty-three in men. It seldom, if ever, occurs under the age of sixteen, but is found in persons of all ages from thus to sixty and upwards. According to Rokitsanski, it is met with more frequently in persons beyond fifty than in persons under thirty. This disease has not been found in conjunction with, or in sequel to, any other disease, with such frequency as to lead us to conclude that it has any intimate connection with it.

Symptoms of Ulcer of the Stomach.—In its early stages these are few and equivocal. Pain and soreness at the stomach felt after meals, occasional acid eructations, and occasional vomiting, which are often the only symptoms then present, may result from various other causes, and even from mere functional disorder. After these symptoms have lasted some weeks or months, their very continuance becomes significant: it leads us to conclude that they depend on organic disease, while the seat of the pain and the circumstance that it is always increased by eating, and usually abates as the stomach gets empty, lead us to infer, in the absence of any direct evidence of disease of the liver or other adjacent organs, that this disease is in the stomach. After a time, these symptoms are often succeeded by the sudden occurrence of vomiting of blood in large quantity. When this has happened, the detection of the disease becomes much easier.

Treatment of Ulcer of the Stomach.—The patient should prevent the ill effects of distention, of change of volume of the stomach, by eating little at a time; and the food taken should be of the mildest kind. Whatever irritates an ulcer of the skin will irritate an ulcer of the stomach. Milk, or milk with bread or with arrowroot, and other farinaceous food, are the articles of food which cause the least pain. Occasionally a little jelly or beef-tea may be allowed. The choice must be determined by the degree of pain which they severally occasion. Medicines are of comparatively little efficacy. When there are sour eructations, or when, in case of vomiting, the matters ejected are sour, fifteen grains of bicarb. of potash and three or four grains of nitre, two or three times a day, lessen the pain at the stomach, and are, therefore, productive of benefit. In vomiting of blood, a few grains of citrate of iron may be often given with advantage as soon as a little solid food can be borne without pain. When the bowels are confined, an aloetic or a compound colocyath pill should be given. If vomiting of blood should come on, ice swallowed, grappled to the epigastrium, alum, &c., with long fasting, are the means most likely to restrain it.

Effects of Galvanism on a Blistered Surface.—Apply two small blisters the size of a shilling, says Dr. G. Bird, to any part of the body, once a

L D, London. Our correspondent ought to state his reasons for requiring the answer he does.

Dr. Frederick Brittan, Clifton, Bristol.—The

work has been received, and will have our earliest attention.

Mr. Thomas Brown, Castle Donnington, is thanked for his communication; the case is an interesting one.

E. J., Piccadilly.—We have not yet received the paper to which he refers.

A Student of the Edinburgh University.—The certificates will qualify for both the College and the Hall. The fee for the certificate is six guineas for the country, and ten for London.

A Dupe.—The debt cannot be recovered in consequence of practising within the prohibited distance without having paid the additional sum.

Mr. Henry Cottrell.—A communication shall in a short time be transmitted. We have not yet decided upon what course we shall pursue.

A Surgeon in General Practice.—Candidates for the Diploma, from the University mentioned, must reside a certain time at the place. The examination is conducted viva voce, in Latin or English, and comprises anatomy, physiology, materia medica, chemistry, pathology, therapeutics, and midwifery.

N. B., West-end.—The penalty for selling patent medicines without a license is, we believe, £20; if there be not also a stamp affixed to the article, so that it cannot be readily removed, £10. Soda, seidlitz, and ginger-beer powders, are not included amongst patent medicines. The license costs £2 for London, Westminster, and Southwark.

A Subscriber from the Beginning.—We are unable to comply with our correspondent's wishes.

Mr. G. Maysey.—The surgeons to county lunatic asylums are, we believe, appointed by the magistrates.

Invalids should state his case. Some medical practitioners, the parties mentioned are quacks, and have probably given a fee to the editors of the newspaper to puff them into notoriety. The undertaking is too profitable to be put down without the interference of the Legislature.

An Apprentice.—Fractures are not unfrequently produced by mere muscular action. The Number required is out of print.

Amicus.—We do not retain manuscripts after they have been used, and communications not inserted are destroyed.

Our friends at Thirsk, we think, must, on consideration, agree with us, that on a matter of merely local interest we should not, in the absence of any new facts, be justified in further drawing upon the attention of our readers.

A Navy Surgeon.—There is good cause for complaint, and we trust that the Government will see justice done. We shall be obliged to our correspondent for his promised communication.

Democritus.—We have not overlooked the case, but shall attend to it when we have received all the details.

Mr. Jackson.—A double qualification is required, though practitioners of 1855, having appointments at the time, were not superseded.

M.D.—An English diploma will be an introduction to the wards of Parisian hospitals, or a passport in which the party possessing it is described as a surgeon.

An M.R.C.S., Ireland.—"To visit, prescribe, and dispense," legally, the Apothecaries' certificate is necessary. Without this, a prosecution may be instituted, and there are many urging the society to use their power, in consequence of some persons boasting that they care not for their certificate, so long as they have the College diploma.

Chirurgus.—The subclavian artery has been frequently tied above the clavicle, and external to the scalenus anticus muscle.

Incog., Liverpool.—The doings of the select vestry are by no means praiseworthy. It is a matter of regret that they should have an opportunity of insulting the profession in the way they have done.

Medico-Chirurgus.—Ergotine has been used in hemorrhage, by M. Bonjean of Chambéry. In one case it stopped the flow of blood in two minutes from a wound in the hand, when compression had been used and found of no avail.

An Advocate for Reform.—It is certainly needed, and the suggestions of our correspondent are plausible.

The correspondent who has written to us on the reason why the druggists supported the late bill, as also the gentleman who expresses his condolence about the non-support of a periodical he names, are thanked for their obliging communications.

A. W. London.—The Editor of the Pharmaceutical Times will give the required information.

J. A., Bury St. Edmunds.—They cannot.

A correspondent has forwarded to us an analysis of the valorous remonstrants to the proceedings of the council of the National Institute. We have not space to publish the document entire; but we are told that of seventy-seven, the total number, five are not members, and thirty-six have not paid their subscriptions! What sort of conscience can these gentlemen have? When a man runs up a score with his baker or his butcher he generally submits very quietly, even to a palpable imposition; his conscience makes a coward of him; but these gentlemen assumed a right to complain before they have established a right to have. When the voracious Dandies had eaten a barrel of oysters, and found that he had no money in his pocket to defray the expenses, he turned round and abused the landlord for the stinginess of the supply. It appears that the race of Dandies is not yet extinct.

A correspondent thus addresses us:—"My attention was particularly attracted by the short allusion made, in the Medical Times of the 12th ult., to the treatment of tania, by M. Rayer, at the Hôpital la Charité, having a patient under my care who has been grievously troubled with it for at least four years. Perhaps it would not be infringing too much on your editorial capacity to request the favour of some further inquiry upon the subject from your Parisian correspondent. The worm is of the tania solium (ascaris marginalibus) kind, and appears of great length, if the numerous fragments occasionally voided be any criterion. The attendant dyspepsia is of the atonic and irritable variety, the gastro-intestinal mucous membrane being highly sensitive and feeble; the bowels rather torpid, though plentiful biliary secretion attends, from the constant irritation present. Acidity, weight, and nausea are constant symptoms, notwithstanding the best-conducted hygiene. The reflex nervous actions are slight, but constant tonic or clonic spasms, with general debility—almost paralysis; the base of the brain being evidently much irritated, interferes to some extent with volition and motion, pulse soft and feeble, easily accelerated. Precordial anxiety, with leanness and loss of strength, is present. The person is of the male sex, thirty years of age, unmarried, and of a delicate and nervous temperament. I am informed that masturbation was practised from twelve to eighteen or nineteen years of age, sometimes to a considerable extent, this no doubt is a predisposing cause; but is the precursor of tania a symptom merely, or a disease to be directly and chiefly treated? The usual remedies—turpentine, pomegranate, oil of fern, and purgatives, &c.—have been tried in all shapes and forms."

Letters and communications have also been received from A. Navy Surgeon; Democritus; Mr. Jackson; M.D.; An M.R.C.S., Ireland; Incog., Liverpool; Medico-Chirurgus; An Advocate for Reform; Amicus; An Apprentice; Invalid; Mr. G. Maysey; A Surgeon in General Practice; Mr. H. Cottrell; A Dupe; A Student of the Edinburgh University; E. J., Piccadilly; Mr. T. Brown, Castle Donnington; Dr. F. Brittan, Clifton, Bristol; L. D., London; Mr. G. Corfe, Middlesex Hospital; A. W., London; J. A., Bury St. Edmunds; Chirurgus; A Subscriber from the Beginning; N. B., West-end.

AMERICAN PATENT.—Among the notices of recent American patents in "Newton's London Journal of Arts" is the following:—"To John Allen, of Cincinnati, Ohio, for a method of restoring the fullness or roundness to the cheeks. The patentee claims as his invention, and desires to secure by letters patent, restoring hollow cheeks to their natural contour and rotundity by means of metallic bulbs, formed, fitted to, and secured in the mouth by any suitable attachment between the jawbones and the cheek."

THE MEDICAL TIMES.

SATURDAY, JULY 3, 1847.

THE MEDICAL OFFICERS OF THE ARMY AND NAVY.

Good service is always entitled to reward, and that of such a kind as shall be in accordance with the principles of justice. In civilized communities the mere payment of money is not always an adequate compensation, there being a species of remuneration, honorary in its nature, yet pleasing to those to whom it is granted, because of the respect and veneration which always accompany it. Men are taken with names as well as things; and what society has, by its all-powerful fiat, invested with value, those who are benefactors to society are entitled to receive in return for their services. Governments, however, which are supposed to be influenced in their conduct by the communities over which they preside, do not always dispense their favours either wisely or justly. Wisdom is knowledge in action, and is manifested by the employment of the best means to accomplish the most desirable ends; while Justice consists in bestowing upon individuals that amount of reward which is proportioned to their deserts. Society is protected by brave and well-disciplined armies, and those whose skill in military tactics enables them to come off victorious in battle are entitled not only to a "lip service" from their countrymen, in the shape of thanks, but to the most substantial rewards which it is possible for a Government to bestow. In the distribution of them none should be exempt, though their efforts may have only contributed indirectly to successful results.

The strength and efficiency of an army depend greatly on the health of those who compose it; and the officers who watch over this, and are enabled by the knowledge which they possess to make efficient and useful soldiers of those who have been disabled in battle, ought surely to come in for no small share of the rewards which the people bestow. The skill of the medical officers of the army and navy has saved this country an immense expenditure of men and money; yet who ever heard of a coronet adorning the brow of a military or naval surgeon, or even a piece of ribbon, the badge of some order, decorating his button-hole? We are not of the number of those who would take honours from those who have won them: their merits add a lustre to the brilliant jewels which compose the stars of the several orders; but, while we feel pleased at their success, we are deeply grieved that the members of the medical profession in the service of the Government should be so lightly esteemed. "Right and obligation are reciprocal," observes Dr. Paley; and if, by the aid of professional skill, numbers of wounded have been healed, and, in climates where pestilence and death seem wafted on every breeze, the sick have been raised to health, who can justly dispute the surgeon's right to honours, and the obligation of the Government to bestow them upon him? It seems, however, that the Executive either does not understand the real worth of their medical officers, or that it is very unwilling to acknowledge and reward it. At the present time medals are preparing for the heroes

of the Sutej; and the veterans who fought under the banner of "the Great Captain of the age" have a prospect of receiving still further proofs of a nation's gratitude, in the shape of increased pensions and additional decorations. They have found in the press, moreover, an advocate which has used its irresistible power to enforce their claims. But who has heard the voice of those members of the profession who are employed in the fleets and armies of the empire demanding some token of gratitude to be bestowed on them, or who among the senators or the press have pleaded their cause? Never can it be said that they have not as well and as faithfully served their country as those who are about to receive a decoration or a medal. In battle their dangers have been as imminent as other officers, and they would be utterly unfit to discharge the duties of attending the sick and wounded without, at least, an equal share of courage and deliberation. But we say that more is required; and it has been exhibited without the aid of those excitements which call into exercise martial courage. To enter into battle with all "the pomp and circumstance of war" requires but an ordinary amount of resolution; but in addition to the perils of the contest to have unceasing converse with human suffering in its most frightful forms, and to be saluted with the constant wail of the wounded and dying, would paralyze the energies of many of whose courage as soldiers none could entertain a doubt. The military and naval surgeons have, under the most trying circumstances of which it is possible to conceive, to pursue their avocations—that of repairing so far as is possible the injuries which the combatants receive in a sanguinary engagement. And yet, while thus employed, they are not permitted to anticipate the honours which are professedly bestowed on the brave and good. A wreath of laurel has never yet been platted to encircle their brows, and among all the monuments which have been erected at the public expense in Westminster Abbey and St. Paul's, to the memory of those who perished in battle by sea or land, we know not of one to a member of the medical profession. And we are compelled to ask, why not? Let the Government answer that question; and if they are about now to withhold from their medical officers the medals and ribbons which are the insignia of honour, let them say if the profession has not done enough to deserve their consideration, or that the science of healing is of less consequence than the science of killing. It is to medical knowledge that we owe so much for mitigating the evils which war inevitably produces, and for discovering the means of holding in check those diseases which have caused more havoc by sea and land than the guns of an enemy.

But why should we wonder that the Government overlooks the claims of its military and naval officers, when it deliberately insults the latter as they first enter the service. Especial care is taken that they shall be well educated, for they must not only possess a diploma, but undergo an additional examination by the Director-General. When, however, they are first sent on board ship, they have to content themselves with the midshipman's berth, and they are actually denied the privileges which naval schoolmasters are permitted to enjoy. It is true that they nominally rank with lieutenants in the army, but their treatment is worse than that of many non-commissioned officers, being compelled to submit to the most wretched accommodation.

Such treatment must not only damp the energies of an honourable-minded young man, but must check that intellectual cultivation which his profession requires, while it will bring into exercise a feeling of contempt towards him by the whole ship's company, which, perhaps, is never entirely removed. Such a state of things ought no longer to continue, and we trust that the profession generally will feel itself bound to use exertions on behalf of the assistant-surgeons of the navy.

No better time can present itself for medical officers in both the services to press upon the Executive their claims to honourable marks of distinction. Amongst them can be numbered men who have benefited their country as much as generals who have fought the most decisive battles, and won the most brilliant victories. Harvey, and Hunter, and Guthrie, are names which posterity will reverence, for their labours will confer blessings upon future generations. Let it not be supposed that Government can long resist the earnest, united, and fair demands of its meritorious officers: they have only to exercise firm and respectful solicitation to secure the object they have in view. A change has come over the spirit of the times; so that those who are placed in authority over us hearken to the voice of the public, and show a deference to its demands. Neither can the example of surrounding nations be lost upon our own country. They are beginning to acknowledge the medical profession as worthy of all honour, and upon its members in their service they bestow titles and rewards. This is wise policy, because the stimulus thus given to the medical staff will urge it to do everything to secure the approbation of those who have titles and rewards at their command. If the Government should, in the distribution of medals which is about to take place, pass by its medical officers, it will be an insult to one of the most deserving branches of the public service, and which ought to be represented by the profession generally. Their cause is ours, and we ought to stand by them in their efforts to obtain a share of that approbation which is so liberally accorded to other officers in the same service. We trust that those medical gentlemen who served in the actions for which the present marks of distinction are to be given, will urge their claims upon the Government; and it will be a high honour for it to admit those claims and reward them.

MEDICAL REMUNERATION.

The profession of this country has for a long time been agitated on the great subject of Reform—one which shall elevate its character, consolidate its energies, increase its usefulness, and advance its respectability. At the present time we are not in a position which commands those respectful feelings, either from the Government or the public, to which our calling is entitled. The surgeons of the army and navy are considered of too little importance to merit the rewards and honours of other officers in the service, and the general practitioners of the empire are treated by the managers of public institutions, and guardians of poor-law unions, as if their attendance upon the sick in eleemosynary institutions were of little value. If we look to the public hospitals of the United Kingdom, we find that their medical officers receive but an insignificant remuneration for the services which they render, while the surgeons employed in attending those who are paupers are paid such

niggardly stipends as cannot fail to be injurious to the sick poor, and is certainly degrading to the medical community. These evils may be attributed in some measure to a want of union amongst the members of the profession, while their numbers are such as to produce so great a competition as greatly to reduce the value of their services. This latter circumstance may be attributed to the reprehensible conduct of corporations to whom the Executive has given the power of granting diplomas or certificates to practise the several branches of the profession. Instead of demanding a high standard of qualification, and of instituting a rigorous examination, inspired by the demon of cupidity, they have endeavoured to make diploma-mongering a profitable business to themselves at the expense of the honour and prosperity of the great body of medical practitioners. The consequence is that professional education has not attained that high standard which it ought, and many have been admitted within the pale of the profession whose principal recommendation has been an ability to pay the required fees for examination. Our corporations have been guilty of betraying the trust committed to their charge, and the consequence is a degrading and injurious competition amongst those who are authorized to practise the healing art.

The present condition of the medical practitioners in Ireland is one which cannot fail to enlist our sympathies in their behalf, and has called forth a powerful remonstrance from upwards of a thousand physicians and surgeons of that kingdom, which has been recently sent to the Lord Lieutenant. In England we find that the medical superintendence of extensive districts is undertaken for a sum which cannot remunerate the surgeon, and it is utterly impossible that the sick poor can receive that attention and those medicines which are absolutely necessary for their ultimate restoration to health. The guardians and the poor-law commissioners may endeavour to shield themselves from just opprobrium by placing upon the medical officer all responsibility; but if medical districts are too large, and medical attendants too ill paid, and as a consequence the poor neglected or improperly treated, we should like to know by what species of logic those who employ the surgeon, at a price for which they know he cannot possibly do justice to himself or his pauper patients, are to be exonerated from blame?

At Liverpool we have a specimen of the miserable working of this system. The guardians there determined to dispense with the services of the honorary medical officers of the parish, because they acted in accordance with the dictates of honour and humanity. The fault with which they are charged is not that of neglecting the poor, but of exhibiting too great a concern for their welfare. Their places, we find, are occupied by others, and the liberal sum of twenty shillings per week is allowed to one of the district medical officers for an additional assistant. Twenty shillings a week! for a man to employ his time and risk his life in attending upon the most frightful and contagious diseases—a mechanic can earn double the sum without incurring any of the danger. And can we wonder at the announcement which the *Liverpool Mercury* has made—that one of the assistants had been dismissed for being intoxicated, neglecting his patients, and giving away some of the parish tickets

for whisky? If there is degrading pay, who can wonder at degrading conduct?

But we have another sad specimen of the state of the profession, and the feeling of the public towards it, in the town of Liverpool. A correspondent there informs us "that an immense number of diplomas and testimonials for the vacant medical officers at the workhouse were received and laid upon the table, when the chairman sarcastically observed, that he thought the committee had better sit *à la fin*. This announcement was received with a shout of laughter—the applications being so numerous as to be ridiculous in the eyes of the rich merchant and tradesman guardians. The desire in which the pile of diplomas excite has a melancholy proof of the position of medical men. Among them, says our informant, are some genuine men worthy of a destiny far better than that of a workhouse surgeon, who, applicable as he is regarded with laughter, whose duties will be regarded with contempt and whose name will probably be discredited with the public consideration. It is time for the members of the medical profession to take to themselves, and to demand such a measure of reform as shall enforce a higher education and a stringent examination, or else they will sink still lower in public estimation."

STATE MEDICINE

LORD MORPETH and the Government have done well of the medical profession by their recent efforts at sanitary reform. They have discovered the truth we have been so long teaching, that our body has in it utilities instead of a nuisance service to the public, and have procured the conviction, that the public health is a matter of importance which should be cared for in the same way as any other department of the public welfare. This public invocation of our aid is a proof for social well-being is the beginning, not the end, of that new era wherein Governments will make it a higher glory to have introduced and infused one large social improvement which will remain for ever, effecting the happiness of unborn generations, than to have achieved a hundred victories in the warfare of mere party politics.

We cannot urge on our medical brethren too warmly the duty of supporting Lord Morpeth in these first steps that Governments have made for progress in the large state utilities of our profession, in view of the social importance of it, and the service to the public it is of.

Lord Morpeth's Town Improvement Clauses Act, which has just received the royal assent, contains the following provisions, which medical men should be interested in.

"The commissioners shall appoint a person, by the title of inspector of nuisances, to perform the duties of the office, and to report to the commission as to the state of the town or district under the provisions of this or the special act, or of the by-laws, and regulations of the commission, or of the extension of any nuisances within the limits of the special act, and the commissioners shall publish the name of any inspector so appointed by them, and shall require him to provide and keep a book in which shall be entered all reasonable complaints made by any householder of the district within the limits of the jurisdiction of any by-law or the provisions of the special act, or of any act incorporated therewith, or the by-laws, rules, and regulations of the commissioners for the preservation of the health and cleanliness, or for the suppression of nuisances; and the inspector of nuisances shall forthwith inquire into the truth of such complaints, and report upon the same to the com-

missioners at their next meeting; and such report shall be entered in the said book, which shall be kept at the office of the commissioners, and shall be open at all reasonable times to the inspection of any inhabitant of the said district or other person interested, and it shall be the duty of the inspector of nuisances, subject to the direction of the commissioners, to make complaints before justices, and take legal proceedings for the punishment of any person who has committed any offence under this or the special act, or under any by-law made by virtue thereof.

The commissioners may, if they think fit, appoint, subject to the previous approval of the council, or of the town commissioners, or of the approval of one of her Majesty's principal Secretaries of State, a person of competent skill and experience, who shall be styled 'the officer of health,' whose duty it shall be to ascertain the existence of nuisances within the limits of the special act, especially epidemics and contagious diseases, and to point out any nuisances or other local causes likely to cause, and continue such diseases, or otherwise injure the health of the inhabitants, and to point out the best means for checking or preventing the spread of such diseases within the limits of the special act, and the best means for the ventilation of churches, chapels, schools, registered lodging houses, and other public buildings within the limits of the special act, and from time to time as required by the commissioners to report to them upon the matters aforesaid, and to prepare any other plan or scheme which may be required of him, and the commissioners, with the sanction of the council, may, if they think fit, appoint the officer of health to exercise the powers of the special act, and the commissioners, with the like approval, may direct the officer of health to remove any such offensive matter.

The Health of Towns Bill, last amended in committee, now before Parliament, contains the following clauses which also should be generally known.

"Be it enacted by the Queen's most excellent Majesty by and with the advice and consent of the Lords spiritual and temporal, and Commons, in this present Parliament assembled, and by the authority of the same, that it shall be lawful for her Majesty by warrant under the royal sign manual to appoint four persons to be, with the first commissioner for the time being, her Majesty's Viscounts and Barons of the Privy Council, and four commissioners for the purpose of executing the provisions of this act, and from time to time to remove all or any of the commissioners so appointed, and to appoint other persons in their stead, and the said commissioners shall exercise the powers of the special act, and the commissioners of health and public works, and the last commissioner of her Majesty's Works and Forests, Land Revenues, Works and Buildings shall be the president of the said commissioners.

And it shall be lawful for the said commissioners of health and public works, or any one of them, to appoint, and at their pleasure to remove, so many inspectors, and also clerks and other subordinates and servants as they shall think fit, subject to the approval of the commissioners of her Majesty's Privy Council, shall deem necessary, and the persons so appointed shall assist in carrying this act into execution at such places and in such manner as the said commissioners shall direct."

"And be it enacted, that the said commissioners of health and public works, as they shall see fit, may cause inquiry to be made into the condition of any town or district in England, especially with regard to the supply of water and drainage thereof, and the best means of improving the same, the prevalent causes of disease therein, and any other matters which they shall think fit to know for enabling them to report to her Majesty whether or not this act ought to be put in force within such town or district."

"And be it enacted, that it shall be lawful for the councils or town commissioners to appoint

out of their own body from time to time such and so many committees, either of a general or special nature, and consisting of such number of persons as they may think fit for any purposes in the execution of this act, which in the discretion of the said councils or town commissioners respectively would be better regulated and managed by means of such committees provided always, that the acts of every such committee shall be submitted to the council or town commissioners for their approval."

"And be it enacted, that the council or town commissioners shall from time to time appoint, subject to the approval of the commissioners of health and public works, one or more physicians or surgeons to be officers of health for their town; and the provisions of the Town Improvement Clauses Act, 1847, with respect to the officers of health thereby authorized to be appointed, shall apply to every officer of health so appointed."

"And be it enacted, that the inspectors shall from time to time, as directed by the commissioners of health and public works, visit any town, district or place, and view and take cognizance of all things done or omitted to be done by the councils or town commissioners in execution of this act, or by the council of any corporate town, or any commissioners or trustees acting under the powers of any act of Parliament for providing cleansing, improving, sewerage, or draining any place, and of all works in progress and completed, and of all rates made and assessed, and of all expenses incurred or omitted to be incurred, and of all by-laws, rules, and regulations made by such councils or town commissioners or trustees, and such of them as he shall have been directed to view and take cognizance of by the commissioners of health and public works, shall attend and inquire into every complaint or objection made by the inhabitants of any town, district, or place, as to the manner of the execution of any works or intended works, or as to the execution of any nuisances, and as to any other proceedings of the councils, town commissioners, or trustees with reference to the purposes of this act, and shall from time to time report to the commissioners of health and public works the proceedings of any such councils, town commissioners, or trustees, and as to the execution of any town, district, or place, and on any other matters relating thereto, in such manner as the commissioners of health and public works may direct."

POISONING BY HYDROCYANIC ACID.

Within a short time since the death of Mr. Shepherd, surgeon, of Worcester, in consequence of having taken prussic acid. The case is interesting in a medico-legal point of view, inasmuch as there was both consciousness and volition after swallowing the poison, and death, so far as could be ascertained, was not preceded either by convulsions or the shock. The deceased, after partaking the wine of the chemist, walked into his back parlour, whither he was followed within two minutes, but the acid had been swallowed, when he mounted to two duchesses of Scheld's strength, and very shortly after some minutes the perfect use of his faculties, and then quietly expired. As the quantity of acid measured out to the deceased was known, and as he was seen to drink it out of the bottle, it became desirable to ascertain its strength, which was accordingly done by Mr. Alfred Laylor, and it was found to be 19 per cent or 2 per cent. The following is an account of the post-mortem examination, conducted by Mr. Pierpoint—

"Countenance (particularly the lips) livid, neck, shoulders, and all the posterior part of the trunk, purple. On dividing the integuments, dark blood flowed freely, the blood of the body universally dark and quite fluid, the lungs loaded with dark blood, which had to a considerable extent gravitated to their posterior portion. The right auricle and right ventricle of the heart, and vena cava, full of dark fluid blood; the left ventricle firmly contracted and quite empty. Five out of six gentlemen did not perceive any

odour of prussic acid upon approaching the body, either before or after it was opened. All the abdominal viscera healthy, urinary bladder half full of urine, which exhaled no unusual odour, brim full, but full of fluid blood. The stomach contained about one ounce of raspberry-coloured looking fluid, and had a strong smell of almonds, the stomach itself, particularly at its cardiac extremity, had a very vascular appearance, and in some of the patches oozing of blood had evidently taken place. Some of the patches had also a brownish appearance."

THE CAW-ME CAW-THE SOCIETY

"Caw-facts in law
Where Caw-facts in law"

At an annual meeting of the Suffolk and Norfolk branch of the Provincial Association, the worthy president (W. H. Crowfoot) is reported to have looked round the assembly of a venture members, and to have expressed his gratification in seeing—

"So many of the members of the association and their friends around him, for they had probably all seen the course and unprovoked attack which had been made on the ground of the association by the *Medical Times*, and they would now be able to form their own opinion as to the character of our proceedings. In the discussion that the association had just strenuously supported the cause of Medical Reform, he would reply that he should be glad if it were so (hears). The association had not found on political purposes."

This worthy President Crowfoot's remarks were apparently with speculative spirit and freedom. Even the presence of such a law student like common sense as Mr. Cross cannot withstand him away from such shipwreck. While in the letters of our classical correspondent "Vox Veritatis," we like pearls to meet the humble propensities—"course." The statement of seventeen members out of two counties to extort wonder is "so many" hesitating to be antagonists with the seven members of the committee of the character of the association at Worcester. Finally, he repeats that the association has done nothing for Medical Reform and that it was not formed for political purposes. Though at that very meeting resolutions and petitions are passed under his presidency in favour of the Registration Bill. [In the last matter is, perhaps, right such petitions and resolutions are certainly doing nothing for Medical Reform.]

We instinctively have some suspicion about the accurate judgment of a gentleman who, reading the *Medical Times*, offers to us opposite opinions, it is, we flatter ourselves, a dangerous presumption that a man has any recorded conviction against him—we know no step more perilous in the way of proving a man blockhead. What, then, shall we say of a person, like this Monsieur Corbeau, differing with us so modestly, and cawing out those differences so consistently and rationally? What but this? Print his nonsense, and leave him and it to the parallel insignificance both so well vindicated.

DR. JORDAN ROCHE LANCIE

We regret to announce the death of this talented medical practitioner. The event took place at his house, in Faringdon-street, on the 2nd ult., after a short illness (malignant sore throat) of two days' duration.

The deceased, besides being known as an M.D., was a licentiate of the Society of Apothecaries, and a member of the College of Surgeons.

For years past he had taken a very active part in the politics of one of the City wards, and consequently was elected a poor-law surgeon to one of the districts, and subsequently a common

councilman. In the latter position a rather celebrated quarrel took place between him and a very well known author (connected also with the poetic M. Carpenter), and in the course of the literary matter, several charges were publicly exchanged and answered, which we need not further advert to.

Dr. Roche's political connection with Medical Reform we seldom saw, from the very prominent part he took at the founding of the Medical Protection Assembly, great hopes were formed that he would reach considerable prominence in his advocacy of that cause. It is needless to say that these hopes were never realized, one of the principal obstacles being the circumstances of his health, his breach with the characters of the *Medical Times*, and circumstances which we have good reason to believe were subsequently a subject of considerable regret with Dr. Roche himself. But it just to add that Dr. Roche's abilities were in some part of the very highest order, his power of command was very considerable, his perception of character remarkably quick and happy, his command of language, we need not say, fully justified, and which he was not only able to use with felicity in the public classes, with which he was connected, but also in the private circles. With his literary and scientific attainments, his comprehensive judgment, his valuable services to every quality of his mind, and his brilliant public career.

It is a sad loss to the medical community, and we are sure that the friends of the cause of Medical Reform will be glad to hear that he has left behind him a large and valuable collection of MSS. and other papers, which will be made available to the public.

A wife and a family are left behind him, and we are sure that his friends will be glad to hear that he has left behind him a large and valuable collection of MSS. and other papers, which will be made available to the public.

H. N. L. D.

We have to read the announcement that the Ministry on the 10th inst. has received from the President of the Council of the General Medical Board, a letter from the New York Dispensary, dated the 10th inst., in which it is stated that the New York Dispensary, in consequence of the illness of the President of the Council, has been unable to attend to the duties of the office, and has therefore been obliged to resign the office.

It is well known that the New York Dispensary, in consequence of the illness of the President of the Council, has been unable to attend to the duties of the office, and has therefore been obliged to resign the office. The New York Dispensary, in consequence of the illness of the President of the Council, has been unable to attend to the duties of the office, and has therefore been obliged to resign the office. The New York Dispensary, in consequence of the illness of the President of the Council, has been unable to attend to the duties of the office, and has therefore been obliged to resign the office. The New York Dispensary, in consequence of the illness of the President of the Council, has been unable to attend to the duties of the office, and has therefore been obliged to resign the office.

LADINBURGH ROYAL INFIRMARY

[The Edinburgh Medical Times]
SIR,—In the *Medical Times* of Saturday last the following statement is made respecting the Edinburgh Royal Infirmary:—"We learn that a form of scurvy resembling this very formidable disease [scurvy] has appeared in the wards of the institution. It has already all but cleared out some of the wards."

The managers of the Royal Infirmary, having had their attention called to this statement, have instructed me to request that you will take the earliest opportunity of giving it the most complete and unqualified contradiction.

I am, Sir, your most obedient servant,
ALEXANDER McDONALD, Treasurer.
Edinburgh Royal Infirmary, June 21.

REPRESENTATION OF THE PHYSICIANS AND SURGEONS OF IRELAND TO THE LORD LIEUTENANT, IN REFERENCE TO THE MEDICAL PROFESSION

[The Edinburgh Medical Times]
SIR, I enclose you a copy of a representation which has this day been sent to the Lord Lieutenant of Ireland, signed by 1030 physicians and surgeons in this kingdom, and I entreat your kind support of it in the *Medical Times*.

I am, faithfully,
W. R. WILDS.

15, Westland-row, Dublin, June 23.

"Dublin, 15, Westland-row, June 10, 1847.
SIR, We beg leave to call your special attention to the accompanying representation, and to request that, should it meet your views, you will, without delay, affix your signature to it and return it to the Lord Lieutenant on the other side, you will also be good enough to procure the signatures of such practitioners in your neighbourhood as may not have received this circular."

We remain, Sir, your obedient servants,
JOHN MOILAN,
R. C. WILLIAMS,
W. R. WILDS.

TO HIS EXCELLENCY GEORGE WILLIAM FREDERICK, EARL OF CLARKE, LORD LIEUTENANT OF IRELAND, AND GENERAL GOVERNOR OF IRELAND.

"MAY I HAVE THE HONOUR TO SAY,—We, the undersigned physicians and surgeons in Ireland, beg leave to call your attention to the accompanying representation, and to request that, should it meet your views, you will, without delay, affix your signature to it and return it to the Lord Lieutenant on the other side, you will also be good enough to procure the signatures of such practitioners in your neighbourhood as may not have received this circular."

We remain, Sir, your obedient servants,
JOHN MOILAN,
R. C. WILLIAMS,
W. R. WILDS.

It is a sad loss to the medical community, and we are sure that the friends of the cause of Medical Reform will be glad to hear that he has left behind him a large and valuable collection of MSS. and other papers, which will be made available to the public.

The New York Dispensary, in consequence of the illness of the President of the Council, has been unable to attend to the duties of the office, and has therefore been obliged to resign the office. The New York Dispensary, in consequence of the illness of the President of the Council, has been unable to attend to the duties of the office, and has therefore been obliged to resign the office. The New York Dispensary, in consequence of the illness of the President of the Council, has been unable to attend to the duties of the office, and has therefore been obliged to resign the office.

We most strongly but respectfully protest against the amount of remuneration offered by the Board of Health to physicians and surgeons for attending fever hospitals during the present epidemic, as, in some instances, five shillings per day have been offered by the Board of Health for the discharge of that onerous, responsible, and dangerous duty.

We need not enlarge on the importance and value of the services rendered to the country by the medical attendants of fever hospitals, neither does it seem necessary to do more than suggest that insufficient and degrading remuneration for professional services cannot fail to injuriously affect the public interests, and we confidently trust that your Excellency will take such steps, as may in your Excellency's wisdom seem fit, to remove those grievances, and cause such remuneration to be awarded to the medical officers of fever hospitals and fever districts, as may be commensurate with the great value and importance of the duties required of them."

THE NATIONAL INSTITUTE OF MEDICINE, SURGERY, AND MIDWIFERY.

The National Institute is established in accordance with the following resolution, carried unanimously, at a general meeting of the members of the National Association of General Practitioners of Medicine, Surgery, and Midwifery, held at the Hanover-square Rooms on the 12th day of August, 1846, viz. :—

"That this meeting hereby declares the formation of a 'National Institute of Medicine, Surgery, and Midwifery,' upon the plan approved by the meeting of the National Association, held at the Hanover-square Rooms on the 17th of April, 1846, and with the objects recited in the report just read. That the Institute consist of those gentlemen who have already signified their intention to co-operate in the formation of the same, with such other qualified practitioners as may join within the specified time, or who may become members in accordance with the future arrangements of a regularly-constituted Council."

THE OBJECTS OF THE INSTITUTE.

The objects which the National Institute is established to promote, are—

- 1st. The cultivation and advancement of the art and science of medicine, surgery, and midwifery, and of the sciences ancillary thereto.
- 2nd. The establishment of a high standard of education and qualification, with a satisfactory test, by efficient examinations, for every individual authorized, by law, to practise medicine, surgery, and midwifery.
- 3rd. The registration of all the qualified practitioners of medicine in actual practice in this country, and the suppression of unlawful and unqualified practice.
- 4th. The introduction of the elective principle in the appointment of the governing councils of the corporate institutions of the profession.
- 5th. The encouragement of friendly intercourse and social concord among the various members of the profession, and especially among the class of general practitioners.
- 6th. The maintenance of the interests, social respectability, and professional status of the general practitioners, and the amendment of the conflicting laws that now operate so injuriously to the repose and welfare of all classes of the profession.
- 7th. The formation of a body competent to negotiate with the Government, in the event of the Right Hon. the Secretary of State determining to grant the general practitioners a Charter of Incorporation.

In order to carry out the foregoing objects, it is proposed:—

- 1st. To adopt a comprehensive and well-considered code of by-laws for the government of the Institution, calculated to produce harmony of sentiment and unity of action among the members, and to discourage, as far as practicable, discreditable acts in connection with the practice of medicine.
- 2nd. In the absence of any legal registration, to publish, or to further the publication, on authority, of a complete register of the qualified practitioners in actual practice.
- 3rd. To form a library for circulation among the members of the Institute.
- 4th. To collect a museum of general and pathological anatomy.
- 5th. To publish transactions, as occasion may require, acquainting the members with the nature and bearings of any legislative changes that may be proposed, and giving them such information of the proceedings of the Institute as may be deemed interesting or useful.
- 6th. To open reading and lecture rooms.
- 7th. To institute prize essays and public examinations on specific subjects; and, by such means, to enlist the zeal and ability of the great body of the profession in the cause of medical and general science.
- 8th. To urge upon the Government the claims

of the general practitioners to corporate rights, and to their establishment in an independent collegiate institution.

CONSTITUTION.—BY-LAWS.

CHAPTER I.

OF THE CONSTITUTION OF THE INSTITUTE.

1. The Institute shall consist of a president, three vice-presidents, a council, members, honorary members, and corresponding members.

2. The members shall be composed of gentlemen who were in actual practice previous to the 1st of August, 1845; licentiates of the Society of Apothecaries; members of the Royal College of Surgeons in England, Ireland, or Scotland, and masters of surgery; doctors or bachelors of medicine of any university of the United Kingdom, and fellows or licentiates of any college of physicians, or members of any faculty of medicine, in the United Kingdom, who shall have been in actual practice as general practitioners in medicine, surgery, and midwifery; or who shall satisfy the council of their qualifications to practise in medicine, surgery, and midwifery.

3. Each member residing within ten miles of the General Post-office, London, shall be enrolled as a metropolitan member, and each member residing beyond that distance shall be enrolled as a provincial member, of the Institute; and wherever any part of a town is within ten miles of the General Post-office, it shall be understood that the whole of such town is within the metropolitan district.

4. Each member shall be entitled to a vote in the election of the council.

5. The honorary members shall not exceed twenty; the corresponding members may be elected at the discretion of the council; but neither honorary nor corresponding members shall be entitled to vote in the election of the council.

6. The council shall consist of a president, three vice-presidents, trustees, treasurers, and forty-eight other members; one-half of the latter shall be practitioners resident within ten miles of the General Post-office, the other half, country practitioners, resident beyond that distance. One-third of the metropolitan and one-third of the provincial branches of the council, exclusive of the trustees and treasurers, to go out of office annually, and the vacancies to be filled up in equal proportions from the respective branches, but the retiring members not to be re-eligible for a year.

7. The president shall be elected by the members of the Institute triennially at a general meeting, and shall be eligible for re-election.

8. The vice-presidents shall be elected by the council from their own body, by ballot. One shall go out every year, and shall not be re-eligible for a year. The election of vice president shall take place at the last quarterly meeting of the council previous to the election of the council for the ensuing year; and at the said meeting the number of vacancies to be filled up shall be declared.

CHAPTER II.

BY LAWS OF THE COUNCIL.

1. The council are empowered to appoint committees for the transaction of special business, to employ such stipendiary officers and servants as may appear necessary, and remove or discharge them; and generally to make such arrangements and issue such orders, not inconsistent with the principles of the Institute and the by-laws herein appointed, as they may deem best calculated to promote the objects of the Institute.

2. The election of the new members of the council shall take place in the month of August of each year, and shall be declared within ten days after the report of the scrutineers.

3. The election shall be conducted by voting papers, in which the names of all candidates for the council shall be printed. The voting papers shall be sent to the members of the Institute ten days prior to the day appointed for the

election, and the members who cannot vote in person shall return their voting papers, unsigned, but authenticated by writing their names on the cover. Any voting paper containing more names than there may be vacancies shall be invalid.

4. No member shall be eligible as a candidate for the office of councillor unless he shall have been recommended by at least two members of the Institute, and unless his name shall have been sent in to the secretary on or before the 31st day of July.

5. No member interested in the sale of any nostrum, or specific remedy, or keeping a shop for the retail of drugs, shall be eligible as a member of the council.

6. The names of the proposed new members of the council, together with the names of the retiring members, shall be read at the annual meeting.

7. Two or more members of the Institute shall be appointed by the members present at the annual meeting to act as scrutineers of the election, who shall report the result of the same to the council.

8. The election shall be decided in favour of those names having a majority of votes; and in case of any two or more members being at the end of the list of the majority, having an equality of votes, the election shall be decided by lot.

9. The names of the retiring members of the first council shall be determined by the number of their attendances at the meetings of the council. Those members whose attendances have been the least during the past year being the first to vacate their seats. Subsequently the vacancies shall occur by rotation; and in case of any greater number than eight, either in the metropolitan or provincial list, having been elected to the council in any year, when the period shall arrive for such members, or any one or more of such members, to vacate their seats, the vacancies shall be determined by the number of attendances as in the first instance.

10. Any metropolitan member omitting to attend a meeting of the council or of a committee, for the space of nine months, and any provincial member omitting to attend a meeting of the council or of a committee, or a general meeting of the members, for the period of twelve months, shall be disqualified to continue a member of the council.

CHAPTER III.

OF THE MEMBERS.

1. No member of the profession who shall have received his certificate, diploma, or degree, subsequently to the passing of these by-laws, shall be admitted a member of the Institute, unless he can produce certificates of his proficiency, both in medicine and surgery, from some recognised institution or institutions, in the United Kingdom, empowered by act of Parliament or royal charter to grant the same, or shall give satisfactory evidence to the council of his proficiency to practise medicine and surgery.

2. Every candidate for admission as a member of the Institute shall send in his name to the secretary, together with his address and qualifications, at least fourteen days before the next ensuing quarterly meeting of the council.

3. The annual payment from a member shall be one guinea, payable in advance, and such payment shall be considered due on the 1st day of August; and in case of the admission of a member subsequently to that date, his payment for that current year shall be considered due so soon as he shall have received a letter from the secretary informing him of his admission.

4. The members shall be entitled to the use of the books of the library, and to access thereto, to admission to the museum, and to all such meetings for the delivery of lectures, as the council may appoint to be held.

5. No proprietor nor vender of any empirical nostrum can be admitted as a member of the Institute.

6. If any member shall not have paid his annual contribution within three months from

the period of its being due, the secretary shall be required to write to such member, informing him of the same, and if he shall not forward his annual contribution to the secretary within one month from the date of such letter, he shall not be entitled, *ipso facto*, to any of the privileges of membership.

7 The council to be empowered to investigate such charges that might be brought against any member of the Institute, together with such defence as he may be disposed to submit, and in the event of its being found that his conduct had been calculated to bring reproach upon his professional character, the council shall be authorized to remove the name of such person from the rolls of the Institute, having first informed him of the result of such investigation, and if, within three weeks after receiving such notice, the said member should in writing demand an appeal from the decision of the council, a committee shall be formed consisting of twelve—one half to be members of the council, and the other half chosen by the person accused from the members of the Institute; and, in the event of such an appeal not being demanded within the specified time, such members shall *ipso facto*, cease to be members of the Institute.

8 The council shall be empowered to recommend to any general meeting the appointment of honorary members of the Institute, who may be gentlemen, eminently distinguished in the sciences connected with medicine, but not of the medical profession.

9 Foreign members of the profession, who have highly distinguished themselves by their writings or labours, may be admitted by the council as corresponding members of the Institute.

CHAPTER IV

OF THE GENERAL MEETINGS

1 The annual general meeting shall be held on the second Wednesday in August, when the report of the council on the state of the Institute shall be read, the names of the retiring members of the council and of the new candidates declared, and such other business undertaken as shall have been specified in the notices issued to the members.

2 Notice of the general meeting shall be given to the members at least four calendar months previously.

3 No member shall be at liberty to propose a motion, unless notice shall have been given in writing to the council at least three weeks prior to the holding of the meeting, and the council shall upon the receipt of such notice, communicate the same to the members in their circular summonses.

4 Notice of any new by-law, or of an alteration of a by-law, shall be given to the council, in writing, at least three weeks prior to their quarterly meeting immediately preceding the general meeting, and the council shall make known the said notice of motion to the members as in other cases.

5 The president and council shall be empowered to summon a special general meeting, when they may consider it expedient, giving due notice of the same.

6 All questions (other than those having reference to the by-laws) put to the vote shall be determined by a show of hands, and shall be decided by a majority of members then present, and in case of an equality of votes, the president shall have a second or casting vote.

7 No motion to form a new by-law, or to alter or revoke a by-law, shall be carried unless two-thirds of the members then present vote in its favour.

8 A special general meeting shall be convened on a written requisition to the council, signed by twenty-one members, specifying the business to be brought forward. Such meeting shall take place within one month from the delivery of such requisition.

CHAPTER V

OF THE MEETINGS OF THE COUNCIL

1 The council shall meet at the offices (or house) of the Institute at least once in every three months, and the secretary shall issue a

summons to each member at least one week prior to the holding of the meeting.

2 The summons sent to the members shall give notice of the business to be brought before the meeting.

3 A special meeting shall be called upon the written requisition of five members addressed to the secretary.

4 Nine members shall form a quorum.

5 All questions shall be decided by a majority of votes; and in case of an equality of votes, the chairman shall have a second or casting vote.

6 The postponement of any motion then under discussion at any meeting of the council (excepting the motion immediately preceding the general meeting), to ascertain the opinion of the absent members thereupon shall be allowed provided that a minimum members are agreed thereto.

7 The meetings of the council shall be continued by adjournment.

CHAPTER VI

OF THE COMMITTEES

1 The committees appointed for special business shall be composed of a equal number of members in and in proportion to the business.

2 In order to avoid the necessity of the frequent attendance of the provincial members of the committee, the metropolitan members shall correspond, when necessary, with the provincial members to ascertain their opinion on questions then under discussion.

Each committee shall cease and determine when it has made its report on the business which it was appointed to transact; and if, in any case, such report shall not have been made, such committee shall notwithstanding, cease on the 1st day of July, in each year; any such committee, however, shall continue to act provisionally until a new committee shall be appointed.

CHAPTER VII

OF THE FUNCTIONS OF THE OFFICERS

1 The treasurer and auditors shall be annually elected by the members, at their general meeting, held on the second Wednesday in August, and they shall be eligible to their several offices. The trustees shall be elected in like manner as vacancies may occur.

2 The council shall forthwith fill up provisionally any vacancy in the office of treasurer, or auditor, which may occur antecedent to a general meeting.

3 The council shall also appoint, at their first meeting after the annual general meeting, a secretary, librarian and curator, and such other officers as they may deem necessary to conduct the business of the Institute.

CHAPTER VIII

THE PRESIDENT AND VICE-PRESIDENTS

1 The president shall preside at all the general meetings and meetings of the council, and regulate the business of such meetings; he shall put every question to the vote, according to the intention of the mover; he shall cause the rules and by-laws of the Institute to be duly observed, and shall sign the minutes of all meetings, in authentication of their correctness.

2 In the absence of the president, one of the vice-presidents, or, in their absence, a member, elected by the members then present, shall preside at the general meetings and the meetings of the council, and perform all such duties as would otherwise devolve upon the president.

THE TRUSTEES

3 There shall be four trustees elected for life, who shall hold in trust the funds and securities of the Institute vested in them; they shall pay into the hands of the treasurer all dividends and interest accruing therefrom, and shall dispose of the funds, securities and property of the Institute intrusted to them in accordance with the instructions of the council.

THE TREASURERS

4 There shall be two treasurers, who shall receive on account, and for the use of the Institute, all sums of money due to the Institute, and shall pay from the moneys in their possession all sums

due from the Institute, upon order of the council at any regularly convened meeting, such orders being signed by three members then present.

5 They shall keep proper books of accounts, with vouchers of expenditure, and shall give all receipts in a prescribed printed form.

6 Such funds as may not be required by the treasurers for immediate use, shall be vested in the name of the trustees in Government or other securities, as the council may direct.

THE AUDITORS

7 The auditors shall annually examine the accounts of the Institute, and present a report of the same to the council.

THE SECRETARY

8 The duties of the secretary shall be to attend the general meetings, the meetings of the council, and the meetings of the several committees, also to keep the minutes of the said meetings, to summon all meetings in conformity with these by-laws, to receive correspondence and to communicate with the members, to procure all public documents and reports under the instructions of the council or the committees appointed to transact the business to which they may relate, and also to order all goods and hire such service, under the direction of the council, as may be required for the business of the Institute. That the secretary be required to attend or provide an efficient substitute, from ten to four daily.

THE LIBRARIAN

9 The librarian shall prepare and adjust the catalogue and attend to the regular circulation of the books; he shall call them in once a year, to ascertain their condition, and collect the fines for their detention, injury, or loss, and generally carry out the business of the library. He shall attend from nine to four o'clock daily.

THE CURATOR

10 The curator shall keep a correct catalogue of the preparations in the museum, duly record all donations, superintend the arrangement and putting up of the preparations, and keep all the proper books for such purposes. He shall be required to be in attendance from nine to four o'clock daily.

CHAPTER IX

OF THE DONATIONS

1 The name of every donor of money, books, or other property to the Institute, shall be entered on the minutes and recorded in a proper register. In the case of books, and of pathological and anatomical specimens, the name of the donor shall, whenever practicable, be placed thereon.

CHAPTER X

OF THE LIBRARY

1 A library shall be under the general management of the council, who shall be empowered to appoint a librarian, to purchase books, and to make such arrangements to increase the efficiency of the library as they may deem proper.

2 A catalogue shall be kept in which the title of each book, its edition, with a proper description of its size and place of publication, shall be duly registered.

3 Each book presented to the Institute shall have the name of the donor placed therein, which shall be also recorded in a book kept for that purpose.

4 Tickets shall be printed leaving blank spaces to be filled up with the description of the book applied for, and duly signed and dated by the applicant, which ticket shall be placed in the hands of the librarian, and returned to the reader when the book is replaced. In the case of provincial members, a written application alone shall be deemed sufficient.

5 The library shall be open every day (Sundays excepted), from nine o'clock a.m. to ten p.m.

6 The books of the Institute shall be circulated among the members under the direction of the council, but each publication shall remain on the library table at least one month before it is allowed to circulate among the members.

SUGGESTIONS

FOR A MORE SIMPLE ARRANGEMENT OF THE

MATERIA MEDICA,

BASED ON ITS PHARMACEUTICAL AND THERAPEUTICAL RELATIONS.

By GEORGE LEITH ROUPELL, M.D.

Cantab., F.R.S., Fellow of the Royal College of Physicians, Physician to St. Bartholomew's Hospital, Lecturer on Materia Medica at the College of St. Bartholomew's Hospital

[Continued from page 346.]

LECTURE III.

Having stated some of the objections which may be urged against the various classifications of the materia medica at present chiefly in use, and my desire, if possible, to suggest some more compendious arrangement, I have now to proceed with the several divisions of my subject. It will be remembered that in treating of the organic materia medica my proposal was to assume the chemical character or the obvious pharmaceutical qualities of our actual medicinal agents as the basis of my orders. Attention was thus to be paid to what was found, or believed, to be the active and efficient portion of the various drugs employed as remedies. Such will, no doubt, eventually constitute, as it alone properly deserves, the name of the materia medica. Practical utility, however, and conciseness were more thought of than a strict adherence to rule or a blind tenacity to a purely chemical arrangement. Some of my divisions may, therefore, on this ground be obnoxious to criticism; but convinced that it is of the highest importance, in order to secure efficiency in treatment, that medicines of real power and definite strength should be exhibited, and satisfied that the action of remedies will alone be successfully studied by accurately watching the operation of our agents thus isolated, I proceed, however imperfectly, with my design. It was suggested that the organic substances used as remedies should be divided into twelve sections, according as their medicinal effects might be due:—1, to an alkaloid; 2, to a neutral bitter principle; 3, to astringent matter; 4, to a fixed oil or fatty substance; 5, to resinous matter; 6, to an essential oil; 7, to gum; 8, to starch; 9, to sugar; 10, to an acid; 11, to colouring matter; and to conclude with some remarks upon 12, albumen as a remedial or therapeutical agent.

To commence, then, now with—

1. Drugs which owe their activity to an alkaloid.

These drugs belong exclusively to the vegetable kingdom, and they contain a series of principles capable of producing results singular in their variety, marvellous at present in their nature, and appalling in their power. These principles deserve the first place in my arrangement, as constituting the most important of our remedies; and a few general remarks upon them as a class may appropriately precede their individual consideration.

The vegetable alkalis or alkaloids have, as their name implies, an alkaline reaction, restoring the blue of reddened litmus, or turning the yellow of turmeric to brown. They are for the most part composed of four elements—oxygen, hydrogen, nitrogen, and carbon. They all contain nitrogen. Oxygen is wanting in some, and these are especially energetic. They all form salts with acids, a state in which they naturally exist. The salts thus formed resemble in many respects those of ammonia, to which, indeed, they might be supposed to owe their alkaline reaction. Ammonia, however, does not exist in them, although it is the source from which they derive nitrogen, to which their alkalinity is due. Two processes deserve notice by which the alkaloids may be procured: by one they are obtained in a pure form, by the other in that of a salt. The first process, namely, that for obtaining the alkaloid in a pure form, consists in adding to a solution containing the vegetable base a stronger inorganic alkali; this combines with the acid, and liberates the alkaloid, which, thus freed, is to be separated afterwards from the other principles with which it may be mixed, appropriate means being employed according as it may be soluble or otherwise in the menstruum used, or as it may be itself fixed or volatile. The second process, that for procuring the alkaloid at once in the form of a salt, consists in substituting for the inorganic alkali a salt composed of the acid, or its elements, which, it is proposed, should take the place of the one naturally in combination with the base. On their admixture double decomposition ensues, and thus the desired salt is obtained, and only requires subsequent purification.

The vegetable bases when pure are for the most part very insoluble. Their salts, however, with the exception of the tannates, are easily dissolved; and are commonly employed. The sulphates, the hydrochlorates, and the acetates, are those chiefly in use. Opinion seems to be divided as to the relative value of these salts: the base, however, and not the acid, is the important part, and easy solubility is the only condition essential for activity. Some of the alkaloids are crystallizable; others amorphous; some again are liquid. These peculiarities will serve me as distinguishing features, and will enable me to divide them into three classes, as

I. CRYSTALLINE ALKALOIDS.

1. Morphia { obtained } Papaver somniferum.

2. Atropia Atropa belladonna.
3. Hyoscyamia Hyoscyamus niger.
4. Solania Solanum dulcamara.
5. Datura Datura stramonium.
6. Strychnia Strychnos nuxvomica.
7. Digitalis Digitalis purpurea.
8. Colchucia Colchicum autumnale.
9. Quina Cinchona hera.
10. Cinchonia Cinchona pelude.

II. AMORPHOUS ALKALOIDS.

11. Aconitina from the Aconitum hepellus.
12. Veratrina " Veratrum album.
13. Delphinina " Delphinium staphis-agria.

III. LIQUID ALKALOIDS.

11. Emetina " Cephalis mecuuapa.
15. Nicotina from the Nicotiana glabrum.
16. Conia " Conium maculatum.

1. Morphia stands appropriately at the head of the list, not only from its importance, but also from the fact that it was the first of the vegetable bases that was distinctly recognised and clearly defined. This was effected by the joint labour of Serturner and Robiquet, a little more than a quarter of a century ago.

Morphia, which is represented by the symbol

+ M, and has for its formula $C_{17}H_{19}O_5N$, is obtained from opium, which, if good, yields to the pharmaceutical chemists of this country from ten to fifteen per cent. When carefully prepared it appears in the form of brilliant rectangular or rhombic prisms. Heat drives off six per cent. of water, afterwards fuses, and finally destroys it. Morphia turns red on the addition of nitric acid, blue by perchloride of iron, brown by iodic acid. It is soluble in alcohol, especially if aided by heat, soluble in fixed alkalis, sparingly so in oil, fixed or volatile, still less in water. Its taste is intensely bitter. By these tests we may readily distinguish morphia from all other substances. It is to be procured, according to the Pharmacopoeia, by the addition of ammonia to the hydrochlorate of morphia in solution.

Morphia, the chief active principle of opium, exerts both a topical and a general action on the frame. It influences by its general action the nervous, the vascular, and the secretory systems, topically it allays local irritation, and controls the movement of the muscles.

The effect of morphia upon the nervous system is in the first instance stimulating, afterwards sedative. The period of excitement varying inversely as the dose is followed by one of calm

pain is allayed, sleep induced, and, if given in too large a quantity, death results with narcotic symptoms. It allays irritability, and thus checks undue vascular as well as nervous action. It controls all the secretions except that from the skin, which it increases, occasioning sometimes also intense itching. The secretions, it would appear, are not only controlled but changed, that from the kidneys, for example, abounding under its influence in lithic acid. The leading indications, then, for the employment of morphia in its various forms and states of combination will be:—

1. Acute and severe pain.
2. Urgent vomiting and violent spasms.
3. Exhausting dejections.
4. High nervous excitement.
5. Great prostration and debility.

As examples of the diseases benefited by the exhibition of the active principles of opium, under the first head may be quoted calculi descending through the various ducts in their passage out of the body, some forms of neuralgia, and malignant organic disease in various parts.

Under the second head we find colic, tetanus, hydrophobia, one class of asthmatic attacks, and inordinate muscular paroxysmal movements.

Diarrhœa, dysentery, pyrosis, diabetes, even hemorrhage, especially that from the stomach and uterus, when kept up as it often is by irritation, will find their place in the third section.

With regard to the fourth head, we have daily examples of the advantage of morphia in allaying nervous excitement. We see it in delirium tremens, in the pervigilum of fever, in the restlessness at certain periods of the exanthemata, and in other states of agitation and tumult.

The employment of morphia as a stimulant is of comparatively modern date in our country, though, as is well known, opium has been employed as a means of intoxication in the East from time immemorial. Its union of stimulating and calmative properties renders it or its principles of great use where powerful shocks or severe injuries have been inflicted on the system, as in burns, or after capital operations. In certain chronic states of debility, cachexia, and exhaustion, when the powers of life seem too feeble to carry on satisfactorily the processes of reparation, no remedy can equal morphia. By its employment the tendency to spread in ill-conditioned ulcers is promoted, and cicatrization takes place. By the use of morphia the excess of urea in the secretion from the kidney is converted into a healthy lithate, and the phosphatic diathesis is corrected.

Morphia is undoubtedly of value as a topical agent, and, in the form of fomentation, plaster, or ointment, is capable of allaying pain and irritation. It is, however, decidedly less efficacious than some other narcotics presently to be treated of. Morphia is very insoluble in water; hence it is rarely used in a pure state. It is given as a salt in combination with an organic or mineral acid. The acetate or hydrochlorate are the salts mostly in use. They are nearly equivalent in their properties, and are probably equally readily absorbed; the stronger acid in the stomach, indeed, may be supposed to supply the place of the weaker organic one; still, critically speaking, the acetate would be the purest, the hydrochlorate containing some codeia, which, contained in opium, is found to stimulate the skin and excite the system. The difference between the action of morphia and of opium, from which it is procured, remains to be noticed, as well as the preparations of both.

Morphia and opium alike are stimulating primarily, and sedative afterwards; alike are astruents (so called), save in the instance of the secretion from the skin, which they promote; alike they fluence the circulating fluids; but the unpleasant effects of opium—headache, giddiness, sickness, waking in alarm, and frightful dreams—are least frequently met with when morphia is employed. It should have been observed that opium is an antiperiodic; whether morphia is equally so may be a question, as it is separated from narcotine, a principle itself capable of check-

ing the paroxysms of intermittent fever. Besides morphia, opium contains two other alkaloids, codeia and paramorpha; three neutral principles, narcotin, narcotin, and meconin; meconic acid, bitter extractive, resin, albumen, gluten, gum, volatile oil, and the salts of lime; potassa, alumina, and iron. The official preparations of morphia are the acetate and the hydrochlorate; of opium, the extract, the tincture, the wine, the confection, the plaster, the liniment, the enema. Opium is, besides, contained in many preparations, as in the compound pills of soap, storax, and ipecacuanha; in Dover's powder, in the compound tincture of camphor, the compound kino and chalk powders, the compound gall ointment, and in the cascarrilla mixture of the Pharmacopœia.

The utility of the syrup, the extract, and the decoction of poppies is also to be referred to the same principle.

It were wearisome to dwell longer on this subject. In conclusion it must, however, be stated that age, idiosyncrasy, habit, and disease, materially influence the effects of morphia, rendering on the one hand enormous doses necessary, on the other entirely precluding its use.

I shall here finish my sketch of morphia, and proceed with atropia in my next.

A COURSE OF LECTURES ON CLINICAL MEDICINE,

Delivered in the Theatre of Wright's College, Birmingham. By SAMUEL WRIGHT, M.D.

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and formerly Senior President, of the Royal Medical, Royal Physical, Hunterian Medical, and Cuvierian Natural History Societies of Edinburgh, &c.

Skin diseases, importance of being able to diagnose and treat them; illustrations of the converse; case of eczema mistaken for itch; acne, from critical causes, in a lady, imputed to drunk-drinking; smallpox mistaken for some unknown ailment; necessity of experience to the correct diagnosis and treatment of skin diseases; case of psoriasis, details of; treatment and comments; effects of arsenic and other remedies; pathology of psoriasis; intentions to be fulfilled in the treatment of it; causes of it; cautions in giving arsenic; severe topical applications to be avoided in general psoriasis; pityriasis, its pathological relation to psoriasis, case of both in the same individual; treatment; syphilis, case of; observations upon; treatment.

GENTLEMEN.—You have lately seen some cases of skin disease successfully treated at the hospital; give me your attention whilst I offer a few comments upon them.

The diagnosis and treatment of cutaneous affections are not of trifling importance; you will find your professional distinction or discredit much related to these things in after life. Should your practice fall chiefly in the way of families of respectability or rank, it will behoove you to be very mindful how you designate or prescribe for their superficial ailments. With the fairer sex especially, there is great sensitiveness on the subject of personal appearance, as the sale of "Rowland's Kalydor" can testify; and to fail to remove their spots or specks, or to impute the presence of these to exceptionable causes, is to lose *casus* with the offended party for ever. I remember, some years back, a physician of respectability being consulted by a lady for a troublesome affection of her skin. After deliberate examination, he told her she had got the itch: she was horrified, and the more so when he informed her that it was a communicable disease, and only to be acquired by contact with an infected party. She protested that she had never in her life been exposed to the possibility of such a thing; but all to no purpose: the doctor maintained that her ailment was itch, and that there was only one way of getting it. In the despair which his unhappy diagnosis induced, the lady willingly submitted to be smeared from head to foot with that execrable

compost, sulphur ointment, and to lie in that coating of filth all night. The next morning she was considerably worse: additionally to a spread of her eruption, sympathetic fever had supervened. Alarmed at this, she sent for another medical man, who immediately discovered that her formidable ailment was nothing more than the simple variety of eczema. I need not say how utterly the first adviser lost the good graces of the patient, and of the many friends to whom she industriously reported his unfortunate error.

An anecdote is related of a distinguished surgeon committing the fatal mistake of suggesting to a titled lady who consulted him for acne, that it had probably arisen from spirit-drinking. If the imputation had been true, the manner of making it was ill-judged enough; but the sagacity of a subsequent adviser led him to refer the eruption to the critical period of the lady's life, and he proved to be correct. You may easily imagine how these two practitioners stood afterwards in her estimation.

I remember being much amused, when a student in Edinburgh, at hearing an Oxford M.D., who had come for the sake of hospital practice, descend upon a singular case of skin disease, as he called it. After a disquisition of some ten minutes or more, during which he told us what the disease was *not*, and that what it really might be, was a pathological question of some "dubity" (so he said), a bluff old nurse cut his learning short with the remark, "Why, it's just a case of smallpox, man." Faith the nurse was right. In the walls of the hospital nothing came of the adventure but a laugh; but suppose the mistake had been committed in private practice, and the merit of the diagnosis had been conceded to an old woman, how would the reputation of the practitioner have stood?

Diseases of the skin are only to be known by an acquaintance, *de facto*, with them. You may look at all the pretty pictures, and read all the descriptions and endless subdivisions of these things, and be no wiser when you have done. If, when you come to diagnose and treat them, you fall back upon your mere library learning, you will be on a level with the operating surgeon who has nothing but book anatomy to aid him. There is no department of the healing art wherein practice is more utterly essential to success, than that of cutaneous diseases. There is only one way in which the subject can be properly taught, or learned, and that is by reference to its living evidences. You will perceive, then, that in the present lecture I must confine myself to the particular cases of skin disease which you have seen treated at the hospital.

The first to which I beg your attention is one of psoriasis. The subject of it is an out-patient who has been under my care for about nine weeks. You saw him this morning. When he first came to the hospital, he furnished an excellent specimen of psoriasis. The eruption appeared in irregular patches, from the size of a sixpence to that of a five-shilling piece, over the knees and the anterior part of each leg, over the elbows and each forearm; his head was completely covered with smaller patches. These were of a dullish red colour, and very slightly elevated above the surrounding skin, where there was no accumulation of exfoliating epiderma; where this collected, the elevation was more considerable, especially in its centre, and the dirty white mass consisted of scales of epiderma variously superimposed, with cracks or fissures running irregularly through the substance. The epidermal scales chipped and peeled off in abundance, leaving the integument beneath, tender, glossy, and of a dull red colour. When they were removed by scratching, the subjacent skin was left sore, bright red, and, sometimes being broken, there was a discharge of ichor or blood, which incrustated and formed a rough dark scab.

The patient was twelve years of age when we first saw him: the disease had existed about seven months. There was nothing obviously to account for it, further than that the lad was

clearly of a scrofulous diathesis. Neither of his parents had ever been similarly affected. He had a pale cachectic look; his tongue had a white fur upon it, and its edges were indented; bowels costive, feces lighter coloured than natural; urine scanty; appetite bad; saliva acid. He was ordered wholesome food, regular exercise in the open air, and to be kept from school until better. The following medicines were prescribed:—

R. Infus. gentianæ, ℥viij.; liq. potassæ, 3j.; liq. arsenicalis, 3ss.; sp. eth. nit., 3ij. Misc. ft. mist. cujus cap. coch. larga duo ter in die.

R. Scammonii, pulv. rhei, aa. gr. xxiv; hydr. chloridi, gr. iv. Misc. et divide in pulv. vj. quibus cap. j. omni mane.

In about a fortnight, there were obvious signs of improvement. The general health was much better, in regard to appetite, strength, and spirits. The eruption was also less—less in its inflammation, and in the amount of its epidermal accumulation. You remember my pointing out these two facts particularly to you. As the biliary and urinary secretions were fully restored, the powders, without the colomel, were ordered, and the following mixture:—

R. Decoct. dulcamaræ, ℥viij.; liq. potassæ, 3j.; liq. arsenicalis, 3ss. M. ft. mist. cujus cap. coch. ampla duo ter die.

This treatment suited very well, and the boy continued to improve for the further period of three weeks, when he came crying one morning, and complained of violent pain in his stomach and bowels. It came on in spasms, and was once so violent that I was obliged to give him a dozen drops of laudanum, and a drachm of *sal. volatile*, in camphor mixture, to relieve his sufferings. His tongue was furred, and epigastrium tender on pressure. I felt suspicious that the arsenic was the cause of this stomach disturbance. In large doses, or when long continued, it is very apt to disturb the digestive organs, and produce severe spasmodic pains, vomiting, and purging. His powders were continued, and the following mixture given.

R. Infusi calumbæ, ℥viij.; ammon. carb., 3ss.; tinct. hyoscy., tinct. opii, aa. 3j. Misc. ft. mist. cujus cap. coch. larg. duo ter die.

In about ten days the stomach had fully recovered, and there was a corresponding improvement in the general health; but the eruption was rather more inflammatory, and the accumulation of epidermal scales more abundant. The powders were continued, and the dulcamara mixture given as before, except that twenty drops of the arsenical liquor were substituted for half a drachm thereof, in the half-pint infusion.

From that time the boy steadily and rapidly improved, both in his general health and in the condition of his skin. When we saw him this morning, his arms were perfectly free from eruption, and only on the knee of one leg was there any irregularity of skin: here the disease showed itself rather like pityriasis—the elevation and redness were scarcely perceptible, and the scales of epiderma were not only much fewer, but much finer, than when first we saw him. I think that in a few days this knee will be quite well. The eruption on his scalp was so much better, more than a week ago, that I advised his mother to have his hair cut short, and his head gently washed, every other day, with white soap and tepid water. To-day we saw very little desquamation, and where the scales had been last detached, the subjacent skin had a natural look and feel, instead of being red and tender. I have no doubt that in course of a fortnight we shall have no need of his further attendance.

Psoriasis is nothing more than a subacute inflammation of the derma. As first manifested, the affected parts are warmer than natural, and there is felt a prickling or tingling sensation. Whether this be dependent upon a change in the nervous or circulatory function of the parts, it is not possible to say: the first change appreciable to the senses of the observer is in the circulation. A blush of bright redness appears, which after a time becomes duller. This is the state of congestion. To this succeeds more

sensible heat and coloration, with slight prickling or itching pains. It is difficult to avoid scratching, but this, however slight, is followed by smarting or direct pain. The inflammatory condition has now supervened. In consequence of this, comes a desiccation and destruction of the epiderma; and the vascular action underneath being morbidly vigorous, the epiderma is reproduced at an amazing rate. Several crops are thus furnished in succession, and accumulating, give to the patches the dirty white, rough, and fissured appearance you saw in the case I allude to. The chops or fissures occur as consequences of the scaly epidermal products not being disposed with uniformity. Their size, and the disposition to be more in one place than in another, render it impossible that there shall not be irregularity in the lines of their distribution.

In the process of spontaneous recovery, or of cure—for psoriasis is capable of both—the first change is a lessening of the inflammatory or congestive action. The scaly patches lose their areolar blush, and the coloured ones grow lighter. The epiderma, therefore, becomes more persistent; and when removed, naturally or by accident, the exposed parts have less redness and sensitiveness than in the more active stages of the disease. This improvement by degrees goes on, until at last the circulatory function of the parts becomes perfectly normal, and there is no more desquamation than consists with the ordinary "wear and tear" of the body.

The causes of psoriasis are many. It is often hereditary, and furnishes no clue to its pathological *radice*. In other cases, its origin is traceable to a scrofulous diathesis or cachexia. These are, perhaps, the foundation of most of the skin diseases that are met with. Innatition will produce psoriasis: so will indigestion, whether derived from redundant, insufficient, or unsuitable food: it sometimes follows chlorosis, sudden chills, ordinary colds, or exposure to great heat. With some people, it regularly appears in the spring; with others, in the autumn.

The local variety of psoriasis appears amongst those who have certain parts of their bodies exposed to noxious influences. You see it in bakers, millers, shoemakers, washerwomen, and various artisans who have to work metallic substances.

Psoriasis dependent upon constitutional causes can only be treated by general means. No local applications are of any use. If in one place they seem to do good, in another they will do as much or more harm. The great object is to find out the cause of the disease. You sometimes meet with cases where well-regulated or reduced living is your best remedy; in others, nutritive food and change of air will suffice; sometimes purgatives are chiefly wanted; sometimes emmenagogues; and again, tonics of the vegetable class: these are generally best prescribed with alkalis, but acids are occasionally preferable. I once cured an obstinate case of psoriasis by a mixture, the chief ingredient of which was lemon-juice.

To the boy of whom I have just spoken, I first gave aperients with colomel, because his bowels were torpid, and his hepatic and other secretions were more sluggish than natural. I gave him the bitter infusion, because the state of his tongue and his appetite told me that a bitter would probably benefit him. I had two reasons for giving him the *liquor potassæ*: first, because his saliva was acid, and he had acid eructations; and secondly, because this extra alkali enables the arsenical liquor to agree better with the stomach. If the *liquor arsenicalis* meet with much acidity in the *prime viæ*, it is pretty sure to cause vomiting or purging, or both. Why I gave the arsenic I cannot tell you, more than this, that I have often given it aforesaid, as others have, with excellent effects. Of its *modus operandi* in relieving or curing skin diseases, I must plead ignorance, and fall back upon the results of experience. I have so many times employed it with good results, that I continue to employ it. Whether its services are to be

considered in the light of a tonic or stomachic, or that mysterious "alterative" we sometimes speak of, or anything else, I am not prepared to say. In giving it, mind not to make the dose too large: give it with an excess of alkali; give aperients at the same time; and stop it directly that gastric or intestinal pains tell you it is becoming mischievous.

Dulcamara possesses slight tonic as well as diaphoretic properties: it is for this reason that I like it in psoriasis, where we generally find a naturally dry skin, and more or less alimentary disorder.

Preparations of iodine, especially the iodine of potassium, of iron, and of sulphur, are often excellent remedies in this disease. So are very small doses of bicloride of mercury.

As I have said, you should avoid topical applications, except of the mildest sort, in psoriasis arising from general causes. The more roughly you disturb the scaly formations, the more obstinately and abundantly will they return. When the itching is intolerable, you may order the parts to be gently bathed with a weak solution of carbonate of soda in tepid water, or tepid camphor mixture. The latter is a very agreeable sedative, and one that I have often found successful. Above all things, caution the patient against scratching the affected parts. If the skin be broken, it is generally difficult of reparation.

Pityriasis is a cutaneous affection very closely allied to psoriasis. In fact it is nothing more than this in a mitigated form. It occurs in the same constitutions, and generally from the same exciting causes. It commences with congestion, and proceeds to subacute inflammation (though more mildly), just as does psoriasis; and, because of the mildness of the abnormal circulation, there is less elevation and redness of the patch; less desiccation, exfoliation, and re-production of epiderma; the scales are smaller and less numerous; and in consequence, there are no fissures.

Psoriasis is prone to affect the muscular parts of the body; pityriasis chiefly shows itself upon the scalp, forehead, and face. You saw a very good case of both diseases in the person of a man named Hines, who came into the top ward of the hospital on the 28th of November last year. His arms, and hands, and legs were extensively covered with patches of psoriasis: the upper part of his face, his forehead, and scalp were completely dusted with the peculiar dandruff of pityriasis. Both, here, occurred in the same individual, and merely differed in their relative intensity. The man was a brassfounder, and had lately been out of work, and indifferently fed. The disease was of five weeks' duration. He was ordered generous diet, and half a pint of ale daily.

R. Decocte dulcamaræ, ℥viij.; liq. potassæ, liq. arsenicalis, aa. 3j. Misc. fiat mist. cujus cap. coch. ampla duo ter die.

R. Pil. coloc. c. 3ij.; extr. hyoscy., ℥j. Misc. et divide in pil. xij. quarum cap. ij. omni nocte.

This was all the general treatment the man had, and on the 23rd of December he left the hospital well. Five days less than a month, he was under medical management, and at the time of his departure there was not a trace of skin disease about him. It is probable that the medicines administered to this patient rendered him some service; but perhaps the greater service was due to his improved mode of living. I am inclined to think thus, from the very obvious change that took place in his general health directly that he came into the hospital.

The only local treatment he had, was a little spermaceti cerate to sundry chops in his hands, that were unusually large and sore. I am not fond of greasy applications in these cases, for they prevent perspiration, and often do more harm than good; but, where the subcutaneous tissue is irritable and unduly exposed, a protection like that afforded by a simple unguent is often valuable. In other cases, again, where the affection is purely local, a very dilute form

of citrine, or any similar ointment, will sometimes change, and finally subdue, the inflammatory character of the timent.

You have lately seen a case of sycosis treated with success. The subject of it, an out-patient named Price, came under my care about three months ago. The disease had then existed for more than a year, and he had been under various treatment without any relief. When we first saw him, the eruption occupied the entire of the lower jaw, and was much to the other, and nearly the same of the upper lip. He had not been able to shave himself for many months, and even the most careful washing of his face aggravated the inflammation, and gave him great pain.

I particularly pointed out to you the characteristics of sycosis, as they were shown in this well-marked case. In one spot we saw the skin tense, bright red; I tunepied—this was the state of congestion, ubacute inflammation; in another, this redness was resolved into patches, which finally became dull red conical elevations—these were intumescent or inflamed sebaceous glands, or hair follicles; in another, these elevations were terminated by distinct collections of pus, and this having become exuded, absorbed, or desiccated, gave rise, in other places, to small dark purplish scabs or crusts. When these had fallen off, or been removed, we found the subjacent surface red, shining, and very tender.

The causes of sycosis are various, and are both general and local. The disease often arises from a scrofulous taint, as in the case of our patient. Cachexia, the gouty and rheumatic diathesis, dyspepsia, irregularities of living, exposure to inclemency, &c., will occasion it. Amongst its local causes, the most common are washing the face, whilst heated, with cold water; exposure of the face to strong artificial heat; the use of a bad razor, or of strong soap. One of the severest cases I ever saw, resulted from a profuse scrubbing of the face with soft soap. I do not think that the exciting causes I have mentioned ever produce sycosis except in cases where there is a predisposition to it.

The disease is essentially one of the hairy tissues, which will perhaps chiefly account for its intractableness. What in another spot would be simple inflammation of the derma, or contiguous parts, becomes in this case the more serious, because of the implication of the sebaceous glands and hair bulbs. Baldness of the part is sometimes a consequence of the disease.

Our patient was enjoined regular diet, and abstention from stimulants. To shave himself was out of the question, but he was directed to be as close as possible in clipping his beard with scissors; not to use soap in washing; and to dab his face with a soft towel, instead of rubbing it dry. The following lotion was ordered to be applied three times a day:

R. Hydrarg. chlorid. gr. ij.; acidi muriatic. m. ij.; mist. amygd. ʒviij. M. ft. lotio. Additionally he had the medicines:—

R. Inf. gentian. ʒviij.; liq. potassæ, liq. arsenicals, aa. ʒss. M. ft. mist. cugus cap. coch. larg. duo ter die.

R. Pil. coloc. ʒi.; Olij. extr. hyosey., ʒj.; pil. hydrarg., gr. i. Misce et divide in pil. xiv. quorum cap. ij. quonvis die.

In less than a fortnight we had some satisfactory evidence of improvement. The congestive and inflammatory tendency was less, as shown by the external appearance, and the patient's own remark, that he had less heat, pricking, and pain in his chin than previously. Further, there were fewer spots of suppuration, and in one or two places a little furfuraceous material had collected. You remember my dwelling upon this, as one of the best features in the manifestations of amendment, and saying that the fact of epidermal desquamation being successive of suppuration was proof that the local inflammatory action was subsiding. Such proved to be the fact. In this case we had not a solitary drawback. The patient systematically improved from the commencement, and, before

two months had elapsed, he was able to shave the lower part of his face without inconvenience. When we last saw him, a week ago, there was nothing of his ailment left, except a spot of hardened cuticle, and darkish desquamation, about the size of a shilling, in the centre of the upper lip. By this time it is probable he is well.

* This case, I think, needs no further comment than what I have already given it. It well illustrates the general features, and especially the pathology of sycosis. The treatment I adopted was simple enough, and was very successful; in another case it might be less so, and some other form might be desirable; but you will gather from my observations what are the leading indications to be fulfilled in all such ailments. Look to their immediate and remote causes, and you will have excellent suggestions and guides of practice.

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART IV.

ABSORPTION AND EXHALATION IN ANIMALS AND PLANTS.

Considerable difference of opinion prevails respecting the particular set of organs to which the functions of absorption and exhalation are intrusted in the living animal. Some physiologists maintain that the veins alone are charged with the performance of these functions, others assign them exclusively to the lymphatic vessels.

It is difficult to account for this diversity of opinion, when we look at the structure of the various organic tissues, and consider the absolute necessity for absorption and exhalation in a large series of inferior animals which do not possess lymphatic vessels.

Absorption in living animals should be regarded as a twofold function, viz., 1, the imbibition of a liquid by the organic tissue in contact with it; and, 2, the transmission of the imbibed liquid into the bloodvessels of the body.

The correctness of this view may be readily demonstrated by a series of simple experiments.

First Experiment.—Take a frog, and keep its inferior extremities immersed for several hours in a solution of prussiate of potash; withdraw the animal subsequently from the liquid, and wash it carefully with distilled water; cut it into pieces, and test the various parts with solution of protochloride of iron; the appearance of a more or less intensely blue spot, wherever you may happen to apply this test, will at once convince you that the solution of prussiate of potash must have penetrated through every part of the body.

Second Experiment.—Take a living frog and keep its inferior extremities immersed for some time in a solution of prussiate of potash; withdraw the animal from the fluid, kill it, and test the viscera and tissues for prussiate of potash; and you will hardly find traces of this substance in the muscular mass of the legs and thighs, whilst the heart and lungs will give the most marked indications of its presence when touched with solution of protochloride of iron.

Third Experiment.—Take a frog, kill it, and immerse it, a few moments after death, in the same solution of prussiate of potash; leave it in the fluid for the same time as in the second experiment, and test the divers parts subsequently for prussiate of potash, and you will find that the heart and lungs do not contain a more considerable quantity of that substance than any other part of the body.

The conclusions to be drawn from these experiments are self-evident. The solution is introduced into the body of the frog (no matter whether living or dead) by simple imbibition; but, in the living frog, it penetrates subsequently into the bloodvessels, mixes with the blood, and is thus carried to the heart and lungs, the central organs of the circulatory system.

As has already been stated, the question

whether the lymphatic vessels alone are endowed with the faculty of absorption, or whether this function is, on the contrary, exclusively assigned to the veins; or, to speak in more distinct and intelligible terms, whether liquids can penetrate directly through the walls of the bloodvessels, or whether, to reach the latter, they are obliged to pass first through the lymphatics, has long been a subject of considerable discussion. Now, as we know of no portion of an organized body that is not endowed with the faculty of absorbing, more or less readily, water, saline solutions, serum, &c., it is evident that the first part of absorption may take place equally through the walls of the lymphatics, as through those of the bloodvessels. This conclusion is confirmed by the revelations of microscopic anatomy, regarding the manner in which the bloodvessels and lymphatics terminate. We know of no fact of a nature to demonstrate the existence of independent extremities in the ramifications of the bloodvessels, which ramifications present everywhere the appearance of a very close and continuous reticular texture, the articular network seeming to merge into the venous network, which latter generally predominates over the former; nor does the lymphatic system terminate in independent extremities, but presents likewise the appearance of an exceedingly fine and close trellis or network. The revelations of anatomy, in perfect accordance with experience, lead us to the conclusion, that the first part of absorption can be effected only by the aid of the porositics peculiar to the structure of organized bodies. It is through the pores of the organic tissues that the absorbed substances find their way to mix with the blood, chyle, and lymph, and are thus, by the common movement of their humours, distributed over the whole body. The experiments of Magendie, Ségalas, and Panizza (which it would be superfluous to describe here) have proved to evidence that the bloodvessels have the faculty of absorption; moreover, that absorption takes place principally through this channel alone.

The fact that certain substances may be detected in the urine of animals a few minutes after their introduction into the stomach, has frequently been relied on as a valid objection against the admission of venous absorption; but this objection falls to the ground when we look at the rapidity of the circulation of the blood.

That, on the other hand, absorption may likewise be effected by the lymphatic vessels, is a fact too well known and self-evident to require the trouble of actual demonstration. We will, therefore, at once proceed to a brief enunciation and exposition of the laws of absorption, that have been deduced from the facts revealed by experimental physiology.

1. Substances are absorbed the more readily the more soluble and minutely divided they are, and the more disposed to enter into combination with the organic juices, and to become constituent parts of the blood.

2. The respective intensity of the force of absorption of the divers organs is determined principally by the greater or less abundance of their vessels, the greater or less flaccidity of their tissue, and the greater or less conducting power of the parts that cover them.

It is evident that by the terms *flaccidity of tissue and conducting power, &c.*, we have to understand here simply the greater or less aptness for imbibition inherent in the texture of the organic tissues; the greater or less abundance of vessels means simply the greater or less number of points of contact between the body that is to be absorbed and the liquid with which this body is to intermix. Thus we find that the lungs, which are of a structure more eminently adapted for imbibition than that of any other part of the animal economy, and possess a highly-developed vascular system, are endowed with the highest degree of absorbent faculty, and are the first to manifest the presence of the absorbed substance. The cellular tissue, likewise, is very permeable to liquids; but, being less well provided with bloodvessels than the lungs, its absorbent action is of less rapid operation than that of the latter

organ. The skin, on the other hand, covered as it is by the epidermis, which is of very compact texture and has no vessels, possesses no great power of absorption, which may, however, be considerably heightened by the removal of the epidermis.

3. The rapidity of absorption proceeds in inverse ratio to the greater or less amount of liquid existing in the organism.

This law of absorption will be readily understood. A heap of sand, thoroughly saturated with a liquid, ceases to imbibe any more of that liquid; and, on the other hand, it imbibes the liquid the more rapidly the further it is removed from its extreme saturation point. Dutrochet left a plant exposed to the air until it had lost by evaporation 0.16 (about the seventh part) of its weight; immersing it subsequently in water, he found that it absorbed, during the first four hours of the immersion, 1.05 grammes (about 16 grains) per hour, and lost by exhalation during the same period of time 0.4 grammes (about 6 grains); subsequently it absorbed only 0.45 grammes (about 7 grains), and lost the same amount by exhalation. Edwards saw frogs absorb water the more rapidly the more weight they had lost previously by transpiration. Magendie reports that a dog, from which he had taken a considerable quantity of blood, died speedily from the effects of strychnia; whilst another dog, into the veins of which he had introduced a large quantity of water, escaped poisoning by that substance (strychnia).

4. Absorption varies, within certain limits, in proportion to the temperature of the absorbing, and to that of the absorbed, body.

Every one knows that hot potions operate more rapidly than cold ones. We also saw that the rapidity and energy of imbibition varies greatly according to the higher or lower temperature of the fluid to be imbibed. Of course, this variation, according to the higher or lower temperature of the absorbing and absorbed body, ranges only within certain limits, since, beyond these limits, the structure of the organic body would suffer decomposition.

5. According to Fodéra, the electric current promotes absorption.

Even admitting the experiments of this physiologist to be perfectly correct, it is by no means easy to account for this supposed influence of the electric current upon absorption; the less so as no such influence is observed when applying the electric current in cases of imbibition. The only fact that may in some measure tend to support Fodéra's results and deductions, is that observed by Porret, viz., the transition of water from the positive to the negative pole of an electric pile.

6. The rapidity of absorption varies according to the greater or less degree of rapidity of motion possessed by the liquid contained in the absorbing vessel.

The function of exhalation is, generally speaking, performed by the same mechanism, and governed by the same laws, as that of absorption. A portion of the liquid imbibed or absorbed by a vessel is constantly exhaled again through the walls of the latter. The amount which thus escapes again, varies according to the nature of the liquid, or, in other terms, to the greater or less facility with which the tissue of the vessel may imbibe it. The exhalation of a liquid contained in an organic vessel will proceed the more or less briskly, according to the greater or less degree of humidity possessed by the external walls of that vessel. The respective energy of exhalation is likewise influenced by the greater or less degree of pressure which a liquid has to sustain, according to the greater or less amount of it contained in a vessel, and which, on its side, it exerts on the walls of the latter.

Edwards has shown that the cutaneous exhalation of animals is in some cases ten times more considerable in dry than in humid air, and that it doubles in passing from 32° to 68° Fahrenheit. He found, likewise, that agitation of the surrounding air promotes the perspiration of animals.

Some of the phenomena of absorption and exhalation observed in living bodies are attended with the transformation of the absorbed or exhaled substance. This is the case in most instances of exhalation, and principally in the secretions.

It would be idle to expect that the physico-chemical knowledge which we possess at present should supply us with a full and satisfactory explanation of the secretory phenomena; the subject of secretion forms as yet one of the most obscure problems presented to us by the animal economy. But, with respect to exhalation, we cannot avoid seeing that a phenomenon analogous to filtration must intervene in its production. If you pour a liquid holding insoluble particles in suspension, upon a filter, the fluid will percolate, whilst the solid matter will remain upon the filter. Anatomical experiments have proved that when arteries or veins are injected with a solution of gelatine, coloured with finely-pounded vermilion, the solution transudes colourless through the vascular walls. Contusions of the skin produce a blackish-blue stain, surrounded by a ring of greenish hue, which is again encircled by a yellow border. This is simply owing to the coagulum of the colouring matter of the blood separating from the serum, which latter fluid is then imbibed by the neighbouring tissues.

It has been stated, in the chapter on Imbibition, that salt water loses a greater or less amount of its salt when filtered through a layer of sand; and that, on the other hand, a solution of carbonate of soda, filtered in the same manner, acquires greater density. Imbibition, capillarity, the simple play of molecular attractions, are, in some instances, capable of overcoming the effects of chemical affinity; why, then, should we entirely disdain the notions of ancient physiologists, who looked upon the secretory organs as simple filtration apparatus?

We shall hereafter have occasion to see that membranes and organized tissues in general permit gaseous substances to pass through them. Fodéra was the first who proved that sulphuretted hydrogen, enclosed in a portion of the intestinal tube, spreads through the whole body of the animal and causes its death.

The existence of absorption in plants may be readily proved by simple experiments with solutions of acetate of iron and prussiate of potash.

All liquids, of whatever nature, are absorbable by plants, with the exception, however, of certain too highly concentrated acid, alkaline or saline solutions, which, by destroying the structure of the plant, of course, annihilate likewise its absorbent faculty.

Saussure's celebrated work, "Chemical Researches on Vegetation," comprises nearly the whole of our knowledge on the important subject of absorption in plants; and this may be summed up in the following propositions:—

1. The roots of plants absorb saline solutions, but in much smaller proportion than water.

2. The introduction of salts into plants is facilitated and promoted by the ablation or alteration of the roots, and, generally speaking, by any fact or circumstance that tends to weaken the force of vegetation.

3. Plants do not absorb in the same proportion all the salts contained in one and the same solution.

The constant presence of certain salts in some plants tends to confirm the correctness of this last proposition; Professor Piria found invariably manganese in the seeds of *Lupinus albus*.

We will now proceed to examine whether the absorption of the nutritive juices through the roots, and the subsequent motion of their juice in the plant, are to be looked upon as simple phenomena of capillarity or imbibition, or not.

At the beginning of spring, the sap ascends from the roots to the leaves through the central part of the trunk; whilst, at the same time, a liquid of different composition from that of the sap, and which is called the *proper juice*, moves in the opposite direction—viz., from the leaves to the roots, passing through the cortical tissues.

These facts may be readily verified by very simple experiments which we need not further particularize here. Hales has demonstrated that the amount of liquid absorbed by a growing plant increases in proportion to the surface of its leaves, which fact he attributes to the evaporation operated through the agency of the latter. The forces of capillary attraction and of imbibition alone will not enable us to explain the ascension of the liquid in

the cut and not arm of the L. open arm of the L. above the level of the fluid in the other arm; which shows the amount of pressure from beneath that supported the mercury—a pressure which can be attributed only to the liquid aspirated by the vine, and subsequently expelled through the cut. This force of *impulsion*, and the escape of the sap through a cut, are facts altogether incompatible with the effects of capillarity and imbibition. We saw in the chapter on Capillary Attraction that the same force which raises a liquid in a capillary tube, cannot effect its overflow and escape from the tube. Dutrochet has demonstrated by a simple experiment that the force of *impulsion* which causes the juice of a plant to ascend from the lower to the upper parts has its seat in the final extremities of the roots. This distinguished physiologist lopped the trunk of a vine, by successive cuttings, even down to the roots, and found the flow of sap continuing; he then removed even part of the deeper roots, and yet the sap continued to flow; and so it did still from some of the smallest radicular filaments that he placed in water. These experiments show that the force of *impulsion* is seated in the *spongioles*. Dutrochet adds that he has discovered in the cortical cells of the spongiola a liquid of greater density than water, and coagulable by nitric acid; whence he argues that the spongiola, or rather the cells encircling them (and which contain this fluid of greater density than water), are to be looked upon as a group of endosmometers, and that the phenomenon of the ascension of the liquid in the plant should be considered simply as endosmotic. In the actual state of the science, this view is the least improbable, although it would be highly desirable to have the identity of these phenomena more clearly and conclusively demonstrated than it is as yet by Dutrochet's observations.

How are we to account for the ascension of the sap in a plant from which the roots have been removed, and of which the lower extremity is immersed in water? Are we to consider it as an effect of imbibition or capillary attraction? The great height to which a liquid may rise in the trunk of a tree is altogether opposed to this view, for we know that the action of imbibition and capillary attraction is confined within more narrow limits than the ascension of the sap in the trunk of plants is found to be.

Hales having observed, in the course of his experiments, that the quantity of juice that ascended in a plant was proportional to the superficies of the leaves, inferred from this fact, that the cause of the ascension resides in the leaves. According to his notion the liquid evaporates from the superficial cells of the leaves, which (superficial cells) obtain thereupon a fresh supply of juice from the adjacent cells, simply by the action of capillary attraction; and the same process of suction continues successively through the whole body of the plant down to the cut extremity.

Dutrochet has demonstrated by experiments that the absorption of plants that have been subjected to a process of drying (of course not carried far enough to alter their texture) does not increase in proportion to the respective degree of exsiccation which they have suffered. This shows that the evaporation or transpiration through the leaves is not the cause of the ascension of the liquid in the trunk of a plant.

immersed in water, or, what comes to the same point, it is not the vacuum in the superficial cells of the leaves (supposed to be created by the evaporation of their contents) that occasions the ascension of the sap. Ascension does not take place unless the vegetable tissue contain a certain quantity of water, which acts, perhaps, *per adhesion* upon the fresh water which is to ascend, just as a wet sponge imbibes more rapidly than a dry one. Dutrochet tried likewise to make dried plants reabsorb the water which they had lost by exsiccation. He found, upon immersing them subsequently in water, that no ascension took place except in those plants that had fully regained their original turgescence. Dutrochet ascribes this turgescence of the cells of the leaves to an action of endosmosis, by which the liquid would be discharged from the leaves in an active manner, and very different from the simple evaporation of a liquid in the air. In conclusion, we have to remark, that Dutrochet has demonstrated, likewise, that the influence of light upon the ascension of the sap in plants is exerted upon the process of respiration and the fixation of oxygen in the vegetable tissue.

All these facts show that the ascension of liquids in plants is not owing simply to imbibition and capillary attraction; the cause of this phenomenon is seated principally in the roots, and likewise, in some measure, in the leaves. It is probable that an endosmotic action takes place in the extremity of the roots. Might not a similar cause occasion the movement of the chyle and lymph in the lymphatics and lacteals of animals—a movement which we know to continue for some time after death?

NEW RENDERING OF THE FRENCH LANGUAGE.

File Dr. Goodfellow's translation of the French edition of "Matteucci," Lancet, June 26, p. 663.

French.—Le Professor Piria a toujours trouvé du manganèse dans les graines du *lupinus albus*.

English.—Professor Piria always found grains of manganese in the *lupinus albus*!

[We will present our readers with other important renderings and discoveries next week.]

CASE OF INJURIOUS EFFECTS RESULTING FROM THE USE OF ERGOT OF RYE.

By ROBERT R. NUTTALL, M.D., F.R.C.S., Fellow of the Royal Botanical and Horticultural Society of Van Diemen's Land, &c.

I regret that want of time must preclude the possibility of my entering on the consideration of the present subject with the attention I feel its merits demand; however, as I contemplate at a future period doing so, I must on this occasion content myself with a cursory survey, glancing as I pass forward at a few of the most striking points of resemblance existing in the present cases, as compared with those recorded as resulting from the use of ergot in other countries. In September last I drew attention to the existence of ergot in very many of our indigenous grasses; (a) and subsequent observation has convinced me that animals grazing on pastures where this state of the herbage exists, and in some localities it is to be found in the greatest profusion, have suffered from its use. In the year 1810, in Trois Croix, in France, an epizootic abortion amongst the cows was noticed by M.

Jodin, as resulting from this cause. That the injurious effects produced on the animal economy by the use of ergot of rye has for many years existed in Ireland, though heretofore no case has been recorded in this or the sister country, will, I think, be rendered apparent. (a)

John Hughes, aged twenty years, was admitted into Dr. Steeven's Hospital, Dublin, on the 17th of June, 1847, under Wm. Collis, M.D., F.R.C.S.L., surgeon to Dr. Steeven's Hospital, &c. &c. His appearance is rather short of good health than otherwise; is of middle height, with light hair, blue eyes, the pupils much dilated; complains of thirst, with occasional cramps in the legs and feet, and a sense of weight and want of tone from the knees down, accompanied with loss of appetite for some days past; tongue slightly creamy on the surface, bowels regular, pulse natural; the sounds over the precordial region are perfectly normal, but convey an impression of slowness of time-taking action; temperature beneath the tongue, 98° Fahrenheit. On examination it is found that the nails have fallen off his thumbs and all the fingers of both hands, as well as one of the lesser toes of the left foot, the denuded parts being covered with flabby granulations, secreting a fetid discharge.

Such was the state of the patient when he entered the hospital; in a few days, under the treatment adopted, the tongue became clean, the thirst ceased, and the cramps in the legs and feet were no longer complained of; in a few days, however, some degree of redness about the parts surrounding the nails of the greater, and some of the lesser, toes of both feet was observed, with a slight degree of reddish-purple colouration beneath the nail. The patient was of opinion that there was nothing whatever the matter with them; and I mention this in illustration of the manner in which the disease advances. On the 27th it was observed that the redness was increasing; that the colouration was becoming more marked; that the affected nails were becoming soft and thin, and that one, evidently in a more advanced stage than any of the rest, had become yellow, and with the point of a probe a sense of fluctuation could be discerned. The patient now expresses his fears that they are going to fall off as those on his hands had done, for the symptoms present are identical. The nail alluded to was removed on the following day without any pain to the patient, and exit given to a few drops of healthy pus. I may here remark that new nails are being formed; that the pupils still remain dilated, and that the other symptoms of nervous derangement have ceased. The patient states that he resides at Calmullin, in the county of Meath, where he occupies a small farm, on which he lives with his mother and sister, their respective ages being fifty and fifteen years; has always enjoyed good health, with the exception of an attack of fever five years since, and in December last of bowel complaint, which lasted five or six days. From the beginning of November last until the latter end of February the family had lived for the most part on bread and tea, the bread being made in (unfermented) cakes, and from rye-meal (amongst which had been mixed a small proportion of wheat meal—five stones in twenty), of a very bad quality, which had grown on ground of an exceedingly poor, marshy nature, where the crops were always subject to blights—last year's crop producing from this cause but two barrels to the acre, an average produce being ten. About the first week in March the flour from this source became expended, and since that time they have lived on cakes made in the same manner, but of wheat flour of a good quality. About the beginning of April he was sensible of "stings of cold" at the ends of his fingers, the nails of which became one after the other of a dark purple colour, but at this time unaccompanied by pain; in about a fortnight or three weeks after this "they began to fester, and

had a terrible burning pain in them"; the pus then issued from beneath and around the nails, which, in about a month afterwards, together with the greater part of his hair, fell off, the integument in that situation being exceedingly tender at the time. He also observed that when he made a full inspiration darting pains were experienced in the fingers of the right hand. About three years since, after eating the same kind of bread, his nails had fallen off; but this had taken place with little pain or inconvenience, the new nails having formed before the old ones were quite removed; and the process was so gradual as not to interfere with his occupation as a labourer. His aunt lost all her nails from the same cause. His mother and sister are at this moment suffering in the same manner; their hair has likewise fallen off.

The same results have been observed from time immemorial amongst persons residing on contiguous farms, when they eat unsound rye, or that produced on grounds lately reclaimed or broken up from pasture lands. Several of his hens had died some time after the rye was thrashed. Horses and cows grazing on the neighbouring pastures are subject to lameness, in the course of which they gradually lost their hoofs. Says he has seen a calf, only a few months old, so affected. Had known several men who lost their nails after having eaten the same description of bread: this was by some attributed to cold, as the men had been engaged forming drains. The same thing had been supposed in his case, but his mother and sister, who had never been so exposed, were just as much affected as himself.

I have thus detailed as nearly as I could, and, in some instances, in his own words, the account given by the patient, who is rather an intelligent young man; and I think that his present state, coupled with the foregoing account, can leave little doubt as to the fact of the disease having resulted from the use of ergot of rye. Here we find three persons, living in the same house, and on the same description of food, and for a like period, similarly affected: we also find this to have occurred before, under like circumstances. We learn that the same thing has been observed for years, as resulting from the use of rye, in seasons when it had been "blighted," or when grown on lands lately reclaimed. The latter is strictly in accordance with the experience of the Abbé Tessier (a)—"*Dans une terre nouvellement défrichée, on fit une belle récolte.*" We find that fowls fed on this grain have died, and that animals grazing on contiguous pastures had become foundered, and cast their hoofs. Like effects have been repeatedly observed by others. M. Roulin, when speaking of the effects of ergot of maize—*maïs peladéro*—says:—"On donne au grain ainsi altéré le nom de *maïs peladéro*, c'est-à-dire, qui cause la pelade: il fait, en effet, tomber les cheveux des hommes qui en mangent, et c'est un accident qui se remarque beaucoup dans un pays où la calvitie est presque inconnue, même chez les vieillards."

"Les mules à qui on présente le *maïs peladéro*, le mangent comme s'il était sain. Si l'on continue à leur en donner, leur poil tombe, leurs pieds s'engorgent, et quelquefois même le sabot s'en détache. Comme, dans cet état, l'animal n'est plus propre à servir on le reléque communément dans des pâturages éloignés des habitations; en ces lieux, la cause de la maladie ne subsiste plus, la santé se rétablit communément, et le pied se recouvre d'un corne nouvelle." In the experience of MM. Dodart, Noel, &c., women appear to have been almost exempt from the deleterious effects of ergot of rye; but it will be perceived by the three cases immediately alluded to, that the Irish ladies have not enjoyed the same immunity extended to their sisters of *la belle France*!

Before concluding these few crude and hastily-thrown-together sentences, I may remark that no symptoms of fever, pain, or inflammation ap-

pear to have ushered in the onset of this disease; the sensation of burning pain did not occur until about the period when suppuration commenced, and that this symptom has not accompanied or followed the separation of the nails of the toes. The time occupied in the casting off the nails of the fingers, after suppuration had commenced, extended over a period of four weeks, while that of the nail of the toe removed since his admission was perfected in as many days.

Our knowledge of the laws under which the action of certain deleterious substances received into the system are augmented or modified, rendered active or inert, injurious or harmless, in different constitutions, circumstances, climates, and localities, is as yet in its infancy—as yet amongst Nature's archives unopened and unravelled; it was not until 1676 (a) that the obvious fact of entire limbs separating from the body in an unaccountable manner, and from no obvious cause, was traced home, and the subtle source of death revealed. Much has been written, many the specious arguments adduced, to support individual opinions; but, after all, what does our knowledge amount to? Do we know what prophylactic means to adopt, what remedial treatment to employ? In truth we do not; and even theory itself, the great wet nurse of all startling wonders—the great rallying point and foundation on which the lighthouse of empiricism rests—has failed us in our hour of need!

FRACTURE OF THE BASE OF THE SKULL.

Reported by W. G. DALGLISH, M.R.C.S.L.,
Late Physician's Assistant to King's College Hospital, and
Surgeon to the Strangers' Hospital, Gravelle, Havre,
France.

Thomas Gibson, aged twenty-one, mason, single, of intemperate habits; admitted into the Strangers' Hospital, Havre, Monday, October 26, 1846.

His comrades who brought him to the hospital stated, that on the 25th, about seven o'clock p.m., being in a state of intoxication, he fell down stairs, and, as they supposed, hit his head against the stone steps. He was immediately taken and put to bed quite insensible, in which state he remained the whole night, continually calling out and moaning.

At eight o'clock the next morning, when I first saw him, he presented the following symptoms:—His face was pale; his skin moist and cold; his head cool; tongue moist and furred, protruded straight, but with difficulty; deglutition not affected; sphincters perfect; no impairment of sensibility or motion, but his memory is confused, and he complains of intense pain over the whole head, but cannot refer it to any particular spot; pupils contracted and sluggish, but acting feebly when exposed to a strong light; blood continually oozes from the meatus of the left ear, around which there is tenderness on pressure; he rejects all food, has no appetite, but complains of thirst; breathing natural; he lies on his back, sometimes shifting to his right side, but is unable to lie on the left pulse 60, weak. Ordered head to be shaved, and ice applied.

R. Hydrargyri chlorid., gr. x.; olei crotoni, gutt. j. statim.

R. Ol. ricini, ℥j.; ol. terebinthinae, ℥j.; decoct. hordei oct., j. Fiat enema utend. quatuor horis post pil.

Towards the middle of the day his bowels were well opened, but the sickness remained as frequent as ever. He complains for the first time of great pain in his back, but of no tenderness along the vertebral column.

27. Has passed a restless night; sickness less; has retained on his stomach a small quantity of tea; pupils less contracted and acting feebly;

(a) The description given by the professors of the University of Marburg in 1697 was, from the use of unsound bread; my memory does not serve me as to what sort of flour it was made from.

the oozing from the ear is less, and not so highly coloured; bowels well opened; his skin is cool; his pulse weak, 60; pain in his back much worse. Ordered dry hot flannels to be applied to the back and loins.

Ten p.m. Skin hot and dry, and especially the head; tongue dry. Curcubit cruent. ℥d 3x nuchæ.

28. Has passed a good night; his head is less painful, and his skin cooler; still complains of thirst, but can only retain the smallest quantity of fluid at a time; oozing from the ear has almost ceased.

Nine p.m. The heat of skin and pain in the head have returned; pulse laboured, 84. V. sectio ad 3xvj., and sinapisms to the neck. Clot large and firm; blood buffed and cupped.

29. Passed a good night; is free from pain; oozing from the ear in large quantity, but not high coloured; his memory is confused, but he talks rationally, and has asked, for the first time, for something to eat; a small quantity of mutton broth was given, which he retained; bowels open; head cool; tongue moist.

R. Hydrargyri chloridi, gr. ij., fl. pil. 4tis horis sumend.

Ten p.m. Continues much the same; no fever, and no pain, except in the back, to which I applied a hot bran poultice.

30. Continues much the same; has taken a small piece of dry toast and a little tea for breakfast; pulse 60; head cool, but, if anything, rather hotter than natural; bowels open; urine copious, high coloured, having a large deposit of pale lithates; oozing from the ear rather less.

Three p.m. Head and skin very hot; tongue dry, deviating to the left side when protruded; speech thick; he wanders a good deal, and moans frequently; pulse labouring, 70; he is continually holding his head with both hands, and turning from one side of the bed to the other; respiration laboured and stertorous; bladder tense. Passed a catheter, and drew off his water. Vena sectio ad 3xvj.

Five p.m. Evidently relieved, as the skin cooler, but he still remains insensible; the blood which had ceased to ooze from the left ear begins to flow again.

Ten p.m. Drew off his water; breathing freer. mous less; surface cooler; has passed a motion under him.

31. Considerably better in every respect water still obliged to be drawn off; speaks with ease and sensibly; head cool; tongue moist has taken some broth with apparent relish oozing from the ear scanty; pulse 60.

Eleven a.m. All the bad symptoms have reappeared; pulse so weak as scarcely to be felt; right side paralyzed, as he merely moves the left leg and arm; mouth drawn towards the left side; teeth so firmly closed as to permit of nothing passing; oozing from the ear has ceased; drew off his water, which was ammoniacal. He continued much in the same state until four p.m., when he died.

Post-mortem Examination Eighteen Hours afterwards.—Over the parietal eminence, under the scalp, about half an ounce of coagulated blood. On cutting down through the scalp to the pericranium, a fracture was observed, extending from an inch below the parietal eminence through the squamous and petrous portion of the temporal bone, passing along the meatus auditorius internus, and involving part of the greater wing of the sphenoid. A large clot of blood of some inches in extent was observed under the seat of fracture, which could be separated into layers, as if the hemorrhage had occurred at different periods. The substance of the brain was healthy, as well as the spinal column. The cause of death in this case was undoubtedly the pressure of the clot on the brain, as all the bad symptoms appeared to have been regulated by the flow of blood from the ear: while it continued, the patient was comparatively easy; as soon as it ceased or diminished, the bad symptoms returned. The division of the clot would also tend to support this opinion, as there were three

layers, which corresponded to the several attacks he had.

SCURVY OCCURRING AT SEA AND ON LAND.

On the 10th of April, three Danish sailors were admitted into the Strangers' Hospital, Havre. They complained of the following symptoms:—Great weakness, languor, loss of appetite, and pain in the head and limbs. In two of the sailors the left knee-joint was the most affected, so much so as to prevent them from using the limb; in the third all the joints were equally affected, but not severely. Their gums were spongy, and bled on the slightest touch; there was also bleeding from the nose, and blood passed in clots by stool, and a number of purpuric spots, much resembling bruises, were perceived about the legs, arms, and body. It appeared that they had just arrived from Patagonia, having been seven months on the voyage, living entirely on biscuits and salt beef. As their cargo was guano, and the stench arising therefrom very offensive, to it was attributed their illness, by the captain, &c. Their spirits were so low that they seemed to take notice of nothing, and it was with difficulty that they could be made to take food; their stomachs so irritable that even the smallest quantity of solid food was rejected. Their thirst was great, the tongue dry and of deep red colour; their stools were of a light colour, but contained clots of pure blood. The urine was phosphatic, soon becoming ammoniacal, but quite free from blood. The skin was dry and almost scaly.

10. For the first day, as their stomachs were very irritable, they were given effervescing monade, and towards evening a small quantity of beef-tea, in which potatoes had been boiled.

11. Passed a restless night, talking and starting in their sleep; have more appetite this morning, and have taken more of the beef-tea, prepared as before, and as much lemonade as they pleased. The pains in the joints and head less violent.

12. Have passed a better night, and have eaten with relish a number of potatoes with fresh meat, for dinner. Pains in the joints less, but the stiffness continues much the same; the diarrhoea has entirely ceased, blood being no longer passed by stool; gums less spongy, but still bleeding on pressure; purpuric spots fading.

R. Ferri citrat., gr. ij.; infus. quassie, ℥j. ter die sumend.

They bore this medicine well, and continued to take two lemons apiece daily, and as many potatoes as they pleased. In ten days from their admission one was discharged quite cured, another three days afterwards, but the third was still unable to straighten his knee. A local vapour was ordered every night, and camphor liniment to be rubbed twice or thrice a day; and a week afterwards he also was discharged cured.

A few days afterwards three French railway labourers were admitted into the Strangers' Hospital with much the same symptoms, all having purpuric spots on their legs, and spongy gums, which bled readily on the slightest touch, and one passed clots of blood with his stools. The spots were of a dull red colour in the thighs, and of a deep purple in the legs, here and there intermixed with livid blotches: these were not effaced by pressure, and were tender, particularly the lower spots. The legs were oedematous, pitting on pressure.

On questioning them it was discovered that they had been living on soup made with bread and water, and sometimes a little grease, and had abstained entirely from vegetables.

They were all placed on much the same regimen as the Danish sailors: stimulating liniments being rubbed on the legs and thighs, and bandages applied; and the citrate of iron mixture in the same dose three times a day.

A purpuric spot in one patient was nearly forming an open sore; but it healed kindly on the application of brandy and hot fomentations. In a fortnight they were all discharged cured.

In the first cases, the three usually assigned causes of scurvy were present—impurity of air, the continued use of salt provisions, and the pri-

THE MEDICAL TIMES.

vation of succulent vegetables. In the three last there was not only insufficiency of food, but abstinence from all meat as well as vegetables. That the last of these, namely, the privation of vegetables, is the chief and usual cause of scurvy, I have pretty well made up my mind, as I have frequently had similar cases since, but not sufficiently aggravated as to have been admitted into the hospital, and have ordered the patients to lay out a portion of their money in vegetables, chiefly potatoes (their earnings not been sufficient to enable them to get meat), and thus, by living on bread and vegetables, have invariably been cured, and a recurrence of the disease prevented.

Unfortunately at this time, on account of the high price of provisions, numbers of these cases come under my notice, and each tends to prove more strongly the idea that the abstinence of vegetables is the true cause of scurvy. The spots in all the cases resembled each other so perfectly that it was quite impossible to discover any difference between those which had originated at sea and those on land.

June 23.

REMARKS ON THE SCURVY ENDEMIC AT NOTTINGHAM.

By W. PHILLIMORE STEPH, M.B.,
Surgeon to the Nottingham Union Hospital.

The existence in this town of that hitherto rare disease, true scurvy, cannot be doubted; and from the numerous, severe, and even fatal cases which have occurred, it may safely be inferred that it is prevalent to a fearful extent in various parts of the kingdom, not only amongst individuals collected in eleemosynary establishments, but also amongst scattered populations, which have been deprived of the use of fresh vegetables during the past winter. It would be superfluous in this paper, intended only as a brief notice of the disease as it now prevails here, to enter into a history of it at former periods, but I consider the remarks made in the quarterly report of the Registrar-General very appropriate for quotation; and, if these returns were more extensively distributed, they would confer corresponding advantages. In the report of the Health and Mortality of 115 districts in England, published on the 29th of January, 1847, there was announced an anticipation of this disease. The Registrar states that "No mention is made of the potato disease having had any direct connection with the mortality. The potato, in a state of partial disease, has no doubt been extensively consumed, without giving rise to any specific malady in man, or, indeed, having any appreciable connection with the disorders of the bowels and liver, which grew prevalent about the time the last crop came into use. The absurd and unfounded fancy, that the cholera epidemic, so fatal to infants at the breast, and old people as well as others, is caused by fruit, or has any connection with the 'plum season,' derives not the slightest support from the observations of the year, when the supplies of fruit were unprecedently scanty. Dr. Baly, the physician to the Milbank Penitentiary, showed, some time ago, that scurvy was very prevalent in prisons from the districts in which potatoes were excluded, and did not exist where potatoes were used. The potato contains a small quantity of vegetable acid, in combination with potash (bitartrate of potash or cream of tartar). It is certain that scurvy, which was formerly common, has almost disappeared since the potato has entered largely into the food of the population. It, now that the potato has grown scarce, this disease, characterized among other symptoms by swollen bleeding gums, again become prevalent, its simple prophylactics should be had recourse to." This anticipation of the disease, now become a reality, and the value of the potato as an antiscorbutic being verified, it is to be hoped that these facts will prevent the public from being dissuaded from the culture of this valuable vegetable, notwithstanding the violent opposition to its use by a late celebrated political writer, and the more recent attempt to encourage its ex-

tinuation by the foreboding of its imaginary annihilation by the so-called aphias vastator.

In the same valuable report, examples are given of the ravages which have been caused by this disease. It is stated that "down to the end of the last century the loss of life in our shipping was immense. The first fleet of the East India Company, out of 528, lost 100 men before and 5 after landing, in the voyage of seven months to the Cape of Good Hope. Anson, in three ships, lost 626 men out of 961, in ten months after leaving England. The men had scurvy, dysenteries, putrid fevers; their limbs dropped off; they swooned and died. In the year 1780, the Channel fleet sent 11,732 sick to Haslar Hospital; 1475 had scurvy, 240 dysentery, 5539 fever. At that time Sir James Saumarez said, 'Neither the ships nor men could keep the sea more than two months.' Captain Cook left Deptford in 1772 with 112 men, sailed round the world, and returned in three years with the loss only of four men by accidents, and one by disease."

It is well known that the means which he adopted to preserve the health of his crew were ventilation, good provisions, good water, antiscorbutics, and lemon-juice.

In this town this serious malady has been and is now prevalent amongst the poorer classes, who have suffered much during the last winter from scarcity and dearth of provisions, insufficient clothing, want of employment, and absence of succulent vegetables; but, from observations made on in-door patients at the workhouse, there can be no doubt but that the absence of the potato and swede turnip has been the real cause of the disease, since the other causes enumerated could not obtain where the diet was good and sufficient, ventilation and warmth well provided, and no disadvantageous alteration except the necessary substitution of rice and Indian meal in place of the usual vegetable. In this union potatoes formed an article of diet until Christmas, and on account of the scarcity, swede turnips were substituted with advantage till the 20th of March; for the same reason, at this period, the latter were discontinued, and during the use of both no symptoms of scurvy were manifested. It then became necessary, on account of the failure of both, to use rice and crushed Indian meal, and the following diet of good quantity and quality was made use of:—For breakfast and supper daily, bread with tea, or milk-porridge; for dinner, Sunday, beef seven ounces, and hominy or crushed Indian meal; Monday, bread with meat broth; Tuesday, suet pudding; Wednesday, hominy with treacle and vinegar sauce; Thursday, beef and hominy or rice; Friday, bread and broth; Saturday, bread and pea-soup. For the aged and infirm, bread and cheese with beer twice a week at supper.

From about a month to six weeks after the disuse of the potatoes and swede turnips, symptoms of scurvy broke out amongst some of those inmates who had resided for a length of time in the union workhouse, characterized by debility, sallowness, and in several instances jaundice, petechiæ, bruise-marks, spongy and bleeding gums, neutral urine of high specific gravity—in some 1.027 at 60° Fah.

The cause of the endemic was apparent, and means were immediately taken to prevent its spread or recurrence. The situation of the workhouse on the new red sandstone, in an elevated position, facing the country; well supplied with water, and well ventilated; dietary sufficient in quantity, no salt provisions of any kind being supplied; the time of year, namely, end of winter and beginning of spring, corresponding with its appearance in other times and countries; the period of a month or six weeks clapsing after the continuous use of farinaceous food; the subsequent dietetic alteration—all tend to strengthen the opinion that the want of a fresh succulent vegetable, containing a vegetable acid, was the sole cause of the malady.

There appeared to me several things worthy of notice: neither children at the breast of those attacked or free from the complaint suffered;

nor children of either sex under five years of age; girls were less liable than boys, but boys, adults of both sexes, and especially old men and women, were subject to scurvy; paralytics have been peculiarly obnoxious to it. The disease commences with debility, inactivity, sallowness of the countenance, and flying pains in various parts of the body, before the gums take on their remarkable appearance. At first the margin of the gum is livid for one or two lines, even when the mouth and lips are anemic, and this appearance resembles the lead symptom, but is not so well defined; the gum swells, separates from the tooth or stump, becomes rounded and spongy, secretes more tartar, and bleeds; in some cases the gums have been so enlarged behind and in front of the teeth that these could not be approximated, the teeth loosen, and the blood, putrefying in the mouth, causes a most fetid odour. These marks of the disease are most apparent where the teeth are carious, or where there are bad stumps; and sponginess with bleeding may exist around molars, whilst the gums encircling the teeth in front, if they are sound, may not be at all influenced. In old and edentulous subjects the gum symptoms do not make their appearance, and I am not aware whether this has been noticed by writers on diseases of seamen. Sailors afflicted with scurvy are generally able-bodied men, and few are so old as to be without teeth, so that thus it may have escaped comment.

In boys, petechiæ appear on the legs, but are often absent when the gums are advanced in the spongy state; ecchymoses are infrequent and slight. In adults both exist, the petechiæ appearing generally before the bruise-marks. In old people these effusions of blood take on a different appearance. In most cases there is universal sanguineous effusion, or congestion of the feet and legs, bruise-marks and petechiæ frequently coexisting.

In a medico-legal point of view, the existence of bruise-marks on the extremities, without any external physical cause, is of importance. Ecchymoses certainly occur at this season from scurvy, of various colours in different individuals, and go through the usual course of bruises, passing from lividity through the usual shades of blue, green, and yellow, and in no way to be distinguished from true contusions, except by taking into consideration the time of year, diet, spongy gums (which do not always exist), and other corroborative circumstances. In a scurvy case which came under my notice, the patient declared the bruise-marks were occasioned by blows which it was known could not have been received for five months previously.

The method adopted to prevent and eradicate the scurvy has been marked with immediate benefit: cabbage instead of Indian meal, green rhubarb with puddings, fresh vegetables to soup, lettuce at supper, and imperial as a diet-drink, were employed, together with citric medicines; but these remedies, so easily procurable and applicable in large establishments, may perhaps with difficulty be procured by a remote poverty-stricken population; and it is thus the more important that this disease, so insidious and protean in its early stages, should be searched for, before its effects become as formidable as those which in former times afflicted the unfortunate seaman.

Nottingham, June 21.

ANOMALIES OF THE CILIARY GANGLION.

By CHARLES HENRY HALLETT, Esq., Demonstrator of Anatomy in the University of Edinburgh.

Whilst executing some dissections of the nervous system in the spring of the year 1846, for Professor Goodair's lectures on Descriptive Anatomy, I happened to meet with an irregularity in the formation of the ciliary ganglion, which attracted at the time but little attention. Since that period two other irregularities in the ganglion have come under my observation, one of

them resembling that previously mentioned so closely in every essential respect as to leave no doubt that the ciliary ganglion is not only liable to deviate occasionally from the normal state, but also that such deviations are of a determinate nature. This circumstance, combined with the belief that future observation will trace similar irregularities in the rest of the cranial ganglia, and that a series of such observations will tend to throw some light on the exact nature and the functions of these ganglia, has induced me to record the anomalies to which I have just referred.

In two of the three anomalies the ciliary ganglion, properly so called, was wanting in both orbits, the nerves usually entering into its formation uniting in a very peculiar manner so as to fully compensate for its absence. The arrangement of the nerves in the first instance was as follows:—

The nasal branch of the ophthalmic division of the *nervus trigeminus*, on entering the orbit, gave off three large ciliary twigs, which, running parallel and external to the optic nerve, passed on to and pierced the sclerotic coat of the eyeball. As the nasal nerve was about to cross over the upper surface of the optic nerve, it furnished a filament of some considerable size which coursed under the optic nerve, between it and the inferior rectus muscle, and gained the inner side of the orbit. Immediately to the inner side of the optic nerve this filament united with one from the motor oculi, and another from the sympathetic nerve. The communicating filament from the motor oculi came, as usual, from the branch which proceeds from the lower division of that nerve to the inferior oblique muscle of the eyeball; and that from the sympathetic nerve was traced coursing along the fourth nerve, from which it at first appeared to be derived, to the carotid plexus. The filament from the nasal nerve and that from the motor oculi were so intimately blended and evidently continuous with each other, that no rigid line of demarcation could be drawn between them. They formed an arch, the concavity of which looked backwards, the convexity forwards. The filament from the carotid plexus joined the concavity of the arch, and probably marked the place at which a ganglion should have been found. From the convexity of the arch, several ciliary twigs passed off which pierced the sclerotic coat of the eyeball to the inner side of the optic nerve; the outermost twig being joined by one from the nasal nerve. No evident enlargement and no ganglionic vesicular nervous matter could be detected at the point of union of the three nerves, nor indeed in any part of their coursing; their junction, in fact, closely resembled that which takes place between the descendens and communicans noni nerves in the neck, the only difference between them being the presence of a nerve from the sympathetic system. (a)

The second example presented similar peculiarities. The only difference between it and that just described was in the course taken by the communicating filament of the nasal branch of the first division of the fifth nerve, which, instead of passing under, ran over the optic nerve, and consequently produced a larger arch, the concavity of which embraced the optic nerve. In all other respects the nerves were connected with each other, and were distributed in precisely the same manner as I have detailed at length in the first example.

One circumstance connected with both these anomalies seems worthy of especial notice, namely, that the ciliary twigs from the nasal nerve entered the outer instead of the inner segment of the sclerotic coat of the eyeball, and those derived from the plexus, which was placed on the opposite side of the orbit to that which the ganglion always occupies when present, pierced the sclerotic coat to the inner side of the optic nerve. The usual distribution of the ciliary

nerves in these two cases was, therefore, reversed.

In a subject the orbits of which I partially dissected last April, for one of the students in the rooms, I was so fortunate as to meet with the very reverse of the foregoing state of parts. The ciliary ganglion was double in both orbits of this subject. The observation is the only one of the kind I have made, but the interest attached to it, when considered in relation with the other and different anomalies, is a sufficient excuse for my giving a brief description of the arrangement of the nerves and ganglia.

The nasal nerve furnished its usual branch of communication to the ciliary ganglion, which was situated in the usual place, and formed in the normal manner. As it passed over the optic nerve, it furnished another branch which ran parallel to the optic nerve, and united close showed itself during the spring of the year to the eyeball with two of the ciliary nerves proceeding from the ciliary ganglion. At the point of junction of these three nerves another ganglion was formed. This second ciliary ganglion was similar in shape to the usual one, was as large, and contained a considerable amount of vesicular nervous matter. It distributed five filaments to the eyeball, which pierced the sclerotic coat above and internal to two other filaments coming directly from the posterior ganglion. The nasal nerve also furnished some ciliary nerves which were unconnected with the others. In the right orbit, an extremely fine filament was given off from the lower surface of the anterior ganglion, which broke whilst I was attempting to follow it to its termination. From the course this filament was pursuing, I had little doubt that it communicated with the lower division of the motor oculi.

The first two observations would appear to favour the conclusion that the ganglia seated on certain branches of the cranial nerves perform the functions of a nervous plexus whose action is peculiarly modified by the intermixture of ganglionic vesicular matter. I had no means of determining whether, in the cases I have related, the functions of the ciliary ganglion had been duly performed by the filaments derived from the arch of junction of the nerves which generally unite to form it, but knowing there can be no material deviation of a nerve, or of a part of the nervous system, from the normal state, with-

out a corresponding deviation of function, and finding, in these cases, a complete nervous plexus instead of the ganglion and that plexus connected directly to the sympathetic system, we may, perhaps, be justified in presuming that they were duly performed. Should it be discovered hereafter that the functions of the ganglion are carried on by the plexus, without any appreciable irregularity, then it may be inferred that, although the vesicular nervous matter appears to modify the action of certain branches of the cranial nerves in such a manner as to adapt them to peculiar purposes, its entire absence would not necessarily induce irregularity in their action, provided the nerves had a direct communication with the sympathetic system of nerves. If, on the other hand, the functions were not properly performed, then it becomes a matter of considerable interest to determine what defects of vision, or what derangements of the eyeball, are consequent on the absence of a ganglion on the nerves. These questions may, perhaps, be solved hereafter by connecting the history of the individuals with the anomalies, should such be found.

SUGAR FOUND IN THE PERSPIRATION, NASAL MUCUS, TEARS, AND CERUMINOUS MATTER OF THE EARS.

By JAMES OGDEN & ELITCHER,
Student at the Manchester Royal Infirmary.

The following is a brief report of the patient who was the subject of experiment.

Ralph Duckworth, aged thirty, a power-loom weaver; he is married, and comes from Blackburn; was admitted into the Manchester Royal Infirmary on the 3rd of May, under the care of Dr. Wilkinson. When admitted he presented the usual symptoms of a confirmed case of diabetes, from which disease he had been suffering for near nine months; it appears to have come on whilst he was convalescent from a severe attack of typhus fever. The skin was very dry, he perspired a little during the nights occasionally; was passing seven quarts of urine in the twenty-four hours, of a specific gravity of 1.053.

He was ordered to have generous diet.

R. Pulvis Doveri gr. iv. in pulv. j. nocte maneque sumend.

Date.	Amount of Urine passed in 24 hours.	Specific Gravity	Amount of Liquid drunk in 24 hours.	Remarks.
May 13	Quarts	1.050	Quarts.	He perspires more during the night; in other respects he continues the same.
17	4 ..	1.035	5 and a pint	Continues to perspire more freely.
18	5	1.034	The same	Perspires much less; no other change.
19	5 ..	1.040		Perspires very little.
20	5 and a pint	1.034		Still perspires very little.
21	and a pint	1.039		Skin generally very dry.
22	The same	1.038		He never perspires now but for a moment or two during the night.
23	The same	1.040		
24	..	1.039		The skin has been constantly dry since the 22nd.
25	4 and a pint	1.038	4 and a pint	Surface dry.
26	The same	1.039	5	
27	3 and 3 gills	1.038	4 and a pint	He has begun to perspire freely during the night.
28	3 and a pint	1.040		Perspiration increased.
29	The same	1.038		He perspires profusely both during the day and night.
30		1.039	The same.	
31		1.040		
June 1		1.037		The perspiration is still more profuse.
2	3 and 3 gills	1.036		From this time up to the close of the report, he has continued to perspire profusely. His general appearance is not improved, is scarcely any stronger; appetite keeps ferocious.
	The same	1.037	The same.	
3		1.039		
	The same	1.039		

(a) These peculiarities were pointed out by Professor Goodsir, in the lecture for which the dissection had been made.

From the 3rd of May, when he was admitted, to the 18th, there was a diminution in the density of the urine of 19°, although he was making

two quarts less urine, and drinking the same amount of fluid, without any improvement. And from the 18th to the close of the report the

quantity of fluid drunk was diminished gradually; so also was the amount of urine excreted in the twenty-four hours, and this without any great increase in the density; at the same time the skin was acting very freely, yet any improvement in his general health was not perceptible.

As an increase of the density of the urine in this disease always indicates an increase in the amount of sugar, so a diminution in the density will indicate a diminished amount of sugar in that fluid.

Hence it has been acknowledged that a diminution in the density of the urine, without an increased amount being eliminated, is very favourable to the patient's recovery, inasmuch as there is less of the "morbid matter" excreted. Although the density of the urine and the quantity excreted since his admission have very greatly diminished, there was no improvement in his general health.

I have endeavoured to account for this by proving that there was not actually less sugar excreted, but that there was less eliminated by the kidneys. On the 17th I requested him to place a piece of flannel, three inches square, in the left axilla (where he said he perspired most). After the flannel had remained in this place for forty-eight hours it was removed, and from this flannel I obtained six grains and a half of crystallized and amorphous sugar, or one grain and one-twelfth as eliminated from each square inch in twenty-four hours. Dr. Carpenter states the surface of the body of a man of ordinary stature to be 2500 square inches. Now, if for the sake of an estimate we suppose the whole body was perspiring at an equal rate, we should thus have 2705 grains of sugar eliminated by the skin in twenty-four hours. This rough way of making an experiment will serve to show that the amount of sugar excreted by the skin on the 17th was rather more than a third of the whole amount of solid matter contained in the urine of that day. A calculation of the solid matter (contained in the four quarts of urine excreted on the 17th), made from the tables given by Drs. Christison and G. Bird, gives 7167 grains as the amount excreted in the twenty-four hours.

In the action of the skin we have an explanation of the diminution of the density of the urine without any actual improvement, and we may, by attending to its action, explain the reason of the fluctuation in the density and quantity of urine, so constant in diabetic cases. From a second experiment made on Ralph Duckworth, when the skin was acting very freely, I obtained 2 1-18th grains of sugar from one square inch: this showing that there is an increased amount of sugar excreted by the skin at the time that there was less eliminated with the urine. And in three cases that I have examined, I have found that this increased excretion by the skin has borne a proportion to a diminished excretion by the kidneys. Hence sudorifics that are used in the treatment of this disease to promote the action of the skin, by so doing afford a large surface for the elimination of sugar, and diminish the amount required to be excreted by the kidneys, but do not really diminish the amount excreted; hence their good is more apparent than real. The tests I used to ascertain the presence of sugar were Frommholz's, Moor's, fermentation by yeast, and in every instance procured crystals, or amorphous mass of sugar, by the evaporation of an alcoholic solution. Specimens of the sugar I have forwarded to Mr. Lumb, surgeon, of Rochdale, and Mr. Milner, surgeon, of Wakefield, both gentlemen being very excellent microscopists; and they have confirmed me in my opinion of the crystals being sugar.

By the means above mentioned I have obtained evidence of the existence of sugar in the nasal mucus, tear; and from ten grains of ceruminous matter, which I took from the ears of Ralph Duckworth, I obtained one grain and a quarter of sugar.

The existence of sugar in the perspiration of diabetic patients was pointed out by Nasse,

Rhein. Correspond. Blatt., 1842; also by Simon in a case where he could not detect it in the saliva. Dr. Francis proved it to exist in the sputa; and previously it had been proved to exist in the saliva and faeces, vomited matter, and the blood; had it not been detected in the last-named fluid, the existence of it in the various excretions would of itself have been sufficient to have led to the inference of its existence therein.

FOREIGN PRACTICE.

Reported for the MEDICAL TIMES by ALFRED MARKWICK, Esq., Surgeon to the Western German Dispensary, and formerly Externe to the Venereal Hospital, Paris, &c.

CANCER OF THE BREAST; OPERATION CONTRA-INDICATED; COMPARATIVE VALUE OF CAUSTICS.

Clinical Remarks by M. Velpeau.

A country woman about fifty-five years of age, lying at No. 2 in Sainte Rose Ward, has again placed herself under our care for a cancer of the breast. When she first presented herself to our notice the tumour was nearer its origin, well circumscribed, movable in fact, was in a favourable condition for an operation. There was, however, no pain in the tumour, and the patient, not understanding why a swelling which caused her no uneasiness should require the use of the knife, refused to submit to the only efficacious remedy which could be proposed to her, and returned into the country. The tumour is now ulcerated, adherent, and probably extends down to the ribs, and the patient is anxious for what she before was unwilling to undergo.

It is an evil which you will often meet with in practice, to find an operation refused at the proper time, and solicited at a latter period when the progress of the disease has rendered it impossible or of doubtful success, especially when the cancer occasions no pain; and this is of more common occurrence, since females always find medical men who will give them advice more in conformity to their taste, to the total exclusion of an operation, or tending to delay its performance. In this respect, this class of practitioners is subdivided into several categories:

we have no other end in view than to give to their patients erroneous ideas of their safety, the result of which is too well known to need any mention they are quacks; others, and these may be conscientious, believe in the radical cure of cancer, at least in certain cases, and thus recommend the employment of internal remedies, before attempting, should that become necessary, the removal of the tumour. It is false to assert that medicine can cause the disappearance of even the smallest cancer, and these pretended cases of cure have been errors in diagnosis; it is only when the nature of the disease is not manifestly malignant that we ought to have recourse to internal remedies. Otherwise, if it be a confirmed cancer, we should be entering a dangerous path, losing valuable time in dissipating or diminishing the swelling of the parts surrounding the tumour, which would have no influence on the ultimate result. This method, then, has no advantage, but its objections are these: a cancer is often at first a local affection; this has been contested, but in my opinion it is a well-established fact. By delay, the disease becomes general, and the cancerous cellule, if it really exist, becomes absorbed, afterwards carried into the circulation, and thence to other organs—infection, in short, takes place.

On the hypothesis even that the cancerous principle pre-existed in the economy, and that the tumour was only a manifestation of it, by removing the tumour, if we did not destroy the principle itself, we at least destroy one of its effects, without any unfavourable circumstance with respect to the activity of the diathesis being the result. On the other hand, as a wound, the operation is without danger, if it is performed at the proper time—shortly after the appearance of the morbid growth, when, for instance, it is not larger than a nut. In this case we relieve the patient from it by a small incision that is scarcely followed by any reaction.

My opinion is, that as soon as the cancerous nature of the tumour is evident, the operation ought to be performed with as little delay as possible. To wait until it has ulcerated and extended, and the glands have become affected, is to compromise the life of the patient as well as the science of surgery. When the glands are merely enlarged, the result is uncertain; indeed, under these circumstances, as we grow older, an operation is not thought of. Young practitioners impute this conduct to the coldness of age, and, full of confidence in the power of the art they are beginning to exercise, they consider as timidity that which is the result of experience. They persevere in their attempts, notwithstanding one or two failures, but at length they begin to alter their opinion—to grow old in their turn. They no longer submit the patient to useless torture.

In the present case the tumour is ulcerated, adherent, probably comprehends the ribs, and there are large ganglions in the axilla. This lymphatic enlargement, which is almost always cancerous, as I have just stated, would have dissuaded me from an operation, if the patient, seeing the fate that awaits her, had not by her entreaties prevailed on me to try the only means she has left, however uncertain it may be. The state of the tumour, particularly its size and depth, forbids its removal with the knife; caustics likewise are not of easy application, but they give less shock to the economy, cause no fever, and, although more painful, are less terrifying to the patient. Which caustic should be preferred? The chloride of zinc paste, the Vienna paste, or that of ferre conca? To the latter there is the danger attached to the poisonous nature of the arsenic of which it is composed; and, although this danger has been exaggerated, still it nevertheless exists, as owned by M. Manéc himself, and in this case the extent of the absorbing surface would still more increase it. Moreover, this paste occasions violent pain and inflammation. The Vienna paste causes an oozing of blood, which causes it to run, and its action is too superficial. That of the chloride of zinc only attacks the fungous tissues, or those deprived of their epidermis; you may hold it twelve months in your hand and feel nothing of it; but, if the epidermis is removed by a blister, the whole hand will be burnt: this is a property not less true than strange. We should, therefore, have been obliged to denude a great portion of the tumour, which would have been a very serious inconvenience; besides, this paste occasions the most atrocious suffering during the whole time of its application, notwithstanding its inventor has stated to the contrary.

The black caustic, composed of sulphuric acid and saffron incorporated together so as to form a homogeneous paste (a), appears to me to have an incontestable superiority over all the others. It destroys the whole of the surface with which it comes in contact; occasions no sanguineous oozing even where the skin is ulcerated and fungous; causes but little pain; the tissues attacked dry up, and suppuration commences with the eliminating inflammation. It is true its application is rather difficult, owing to its adhering more to the spatula than to the tissues. As it burns everything, diachylon plaster cannot circumscribe it, and can only be conveniently applied on a horizontal surface; in other situations it would in all probability run. Still these faults, which I am far from wishing to conceal, by no means counterbalance its good qualities. Indeed, I believe the black caustic is better than any other.

ON DYSPEPSIA.

By METCALFE JOHNSON, Esq., Lancaster.

I have had occasion to notice a number of cases of dyspepsia which appear to have origin in a cause often, I think, little suspected, and hence overlooked by practitioners. They con-

(a) This is Velpeau's Ethiopic caustic, or black cauterizing pomade.

stitute a set of cases which often baffle the best-directed efforts at cure. I mean scybalous colic in the colon.

There is a series of symptoms accompanying this affection which may be divided into two sets, primary and secondary.

The primary are the result of mechanical causes, while the secondary are sympathetic.

The primary symptoms are—1st. A sense of pressure from within the abdomen at about two inches above the internal abdominal ring. 2nd. Pain at a spot above the sacro-iliac synchondrosis, called by the patient "pain in the loins." 3rd. Pains in the various branches of the sciatic nerve, most commonly known to the patient as "pain in the legs," but seldom noticed by himself as anything particular, and most frequently felt on the left side.

The secondary symptoms are—1st. A pain (after meals) situated in a spot midway in the sternum between the sterno-clavicular articulation and the ensiform cartilage. 2nd. A sense of distention over the stomach. 3rd. Pain (and soreness on pressure) about an inch to the right of the ensiform cartilage, or in the hollow beneath it: this pain comes on from half to three quarters of an hour after a meal. 4th. Pain under the lower angle of the scapula, or over the coraco-humeral joint, known as connected with hepatic congestion. 5th. A general sense of coldness in the back.

The cause of the primary symptoms seems evident. The pressure of bowel, distended with hardened scybalæ upon the anterior parietes of the abdomen, causing the sense of pressure, and the pressure upon the pelvic nerves giving rise to the pains in the back and legs as described by the patient. This may occur on either side, and seems situated either in the ilio-cæcal pouch, or sigmoid flexure of the colon, or both.

The causes of the secondary or sympathetic symptoms are not so evident, though they may admit of some explanation. The pain in the sternum is often accompanied with acid eructations, and seems to be sympathetic with an irritable state of the stomach, accompanied with excess of acid in the gastric secretion, as alkalis relieve it most speedily. The distention is probably mechanical, from gaseous exhalation. The pain below the ensiform cartilage is apparently referrible to the pylorus. These symptoms I have so often found associated with the accumulation of scybalæ, that I look upon it in great measure as cause and effect.

There is also another source of dyspepsia in females which is much neglected—I mean leucorrhœa. This is mostly accompanied by a sense of pain and weight in the left hypochondrium. The leucorrhœa and dyspeptic symptoms are generally speedily removed by an astringent, either local or internal.

The above remarks refer to cases often but lightly regarded; but in country practice they form three-fourths of a man's practice, and often upon the skilful or unskilful treatment of them his success may rest.

REPORTS ON THE DISEASES OF FEMALES.

By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

I propose to offer one more case of fungoid disease, for the purpose of illustrating the occasional efficacy of escharotics in these affections. I say "occasional," because, as with the ligature we only occasionally meet with cases which admit of their application, and still more rarely with cases which are decidedly benefited by such treatment. The following case is therefore, the more interesting, as the local affection was apparently entirely removed, and two years and a half have elapsed without the patient experiencing any indication of its return.

The case has been drawn up solely with a view to illustrate the local treatment and its effects; it

is, therefore, imperfect in many details, which I now regret. I must, therefore, give it as it is.

M. P., aged fifty-five, married, mother of eleven children, the youngest of whom is twelve years old; miscarried frequently, once between the birth of almost every two children; ceased to menstruate four years ago.

Feb. 15, 1841. Nearly twelve months since, viz., April, 1843, was attacked with a violent and incessant itching in the vulva, which lasted for three months, unrelieved by remedies, and was followed by a sensation of burning heat and swelling in the vagina, although no perceptible swelling existed. She also suffered from dragging pains in the hips and loins, and shooting pains in the thighs and legs, especially the right; also from pains in the epigastrium, breasts, and anus. Had incontinence of urine three months which lasted but for a few days.

Examination per Vaginam.—A livid fungoid growth may be seen and felt on the anterior lip of the os uteri; it is of a conical shape, the diameter of its base being about that of a shilling. It bleeds readily, but not profusely. Argenti nitras has been applied once a week for some little time, but only with the effect of retarding its growth, and not of reducing its size. A thin discharge remains for a few days after the application.

Applicatur argenti nitras ori uteri bis in septimanâ.

The nitrate of silver was applied pretty regularly twice a week until the beginning of April, when, finding that its effects scarcely counterbalanced the rapid growth of the tumour, it was determined to discontinue the caustic for a while, in the hope of being able to cut off the growth by means of a ligature, and then apply it to the surface where the separation had taken place. This plan, however, did not succeed; her general suffered, and the local symptoms increased. The caustic was again resorted to every other day, and with such good success that the fungoid growth gradually disappeared under its effects, leaving a tolerably deep indentation to mark its site, which, on the discontinuance of the application, healed to all appearance in a healthy manner. She has been examined two or three times since, and no trace of the disease beyond a depressed cicatrix can be perceived on the os uteri. Some months after quitting the hospital for women, she was attacked with jaundice, and recovered with some difficulty; since which, her chief complaint has been cough of a bronchitic character.

It is not often that we meet with an isolated tubercle of a malignant character so within the reach of local applications; but I feel confident, from this and other somewhat similar cases, that when occurring under such favourable circumstances much good, if not a complete removal of the disease, may be effected by the use of escharotic applications. A somewhat similar case occurred to me shortly afterwards. A patient sent for me, complaining of darting pains in the centre of the pelvis, and many of the symptoms of inflamed cervix. On examination I found a hard pea-like tubercle imbedded in the structure of the os and cervix, which appeared to be the centre from which her lancinating pains radiated; although not very tender to the touch, examination with the finger brought on a paroxysm of these pains, which lasted for some time afterwards. The cervix, although not inflamed, was in an irritable state, depending apparently on the presence of this morbid growth; a stick of lunar caustic was rubbed upon it for some moments; a thick white slough was produced, and from that moment the lancinating pains ceased entirely, and the tubercle became nearly, if not quite, imperceptible.

CASE OF LARGE ABSCESS OF THE LIVER SUCCESSFULLY TREATED BY PUNCTURE.

By CHARLES CLAY, M.D.

Matthew H., of Stockport, applied to me in September of last year, in consequence of a

fixed pain and fulness in the right and superior corner of the umbilical region; for which he had been purged, bled, and blistered, but without obtaining any relief. His bowels were inclined to be constipated, and the excretions very light coloured; countenance yellow, spirits low, appetite bad, thirst, occasional sickness; pulse 90, not very full; difficulty of lying on either side, particularly the right. There was evident enlargement of the liver, little or no bile secreting. I ordered him the following:—

R. Fel. bov. inspiss., 3ij.; hydr. chloridi, gr. x.; div. in pil. xvii. capt. j. ter die; together with an acidulated quinine mixture, and occasional mustard cataplasms over the region of the liver.

By a steady use of these means the case soon assumed a different aspect, the pain left his side, the countenance improved, bowels regular, appetite returned; in fact, he so far recovered as to leave home for the seaside, where I had advised him to go; whilst there he felt tempted to bathe, but communicated by letter with me. I desired him not to bathe, but to content himself with change of air and scene; but the weather became so hot that he risked bathing. In the evening of the day he took the bath, the former fixed pain again came on with great violence. Bleeding and blistering were again resorted to, but little relieved, and he returned to place himself under my treatment.

The same plan, with calomel and ox-gall, soon restored him to health, and for some time I saw nothing more of him. It appears, however, at the close of the year he visited some relations in Dublin, and whilst there suffered a severe relapse; the pain was acutely violent; the swelling large, very tense, and circumscribed, hard to the touch; all the accompanying symptoms were much aggravated, with the addition of great difficulty in breathing. He was taken to one of the principal hospitals in Dublin, and every active treatment prescribed, but with little or no relief; the swelling increased, but no tendency to fluctuation. It must be remarked, that he had never had any shivering, or any other indicating formation of pus; still, about two inches above the umbilicus, and about one inch and a half to the right side, a point presented itself, very much resembling a male nipple, but larger, tense or rather elastic to the feel, and of a bluish tinge. Two or three consultations were held upon the case, and it was thought the point might be advantageously punctured; but no one offered to do it, although the time was more than once fixed for the operation. Eventually the case became stationary, and it was sent from the hospital as one in which little could be done. The patient now returned home and consulted me. My first impression was that of surprise, that it had not been punctured, and my only hesitation now arose from the opinion given by a combined staff of a large hospital. I saw plainly treatment by medicine was now out of the question, I therefore took a plaster cast of the external surface, and fixed a time for opening. On the 2nd of December I passed a fine grooved needle into the most prominent point, and discovered a small drop of pus; on which I penetrated the part with a moderately-sized trocar, and obtained four pounds of pus, having a most nauseous effluvia. When entirely emptied, a long strip of lint was introduced into the cavity. For four days it discharged a pound of pus at each dressing, and for four more days about half a pound; these gradually decreased to a mere trifle; it was, however, full three months before it entirely ceased, during which time the constitution suffered severely from its debilitating influence, and it was only by powerful tonic mixtures of quinine, with occasional doses of the inspissated ox-gall and calomel to rouse the liver to healthy secretion, that the system eventually improved gradually; the function of that organ was restored, and as that took place the countenance and general health followed step by step, the bowels became regular, and the motions bilious. From the moment the chalky character left the excretions the man began to fatten; he is now stouter-looking than perhaps he ever was, and

has been for some time at his employment, enjoying the best of health. The amount of pus purged with in this case could not be less than from fourteen to sixteen pounds. Perhaps there are few cases where so extensive an affection of the structure of the liver was followed by so complete a restoration of its functions.

101, Piccadilly, Manchester.

MENSTRUAL DISCHARGE IN THE MALE.

By THOMAS BROWN, Esq., Castle Donnington.

John Pegg, aged forty-one, a sawyer by trade, requested my advice relative to a profuse discharge of blood (*per anum*) which periodically returned once a month. The man is father of a family, and suffers no interruption of good health. He has no recollection of hearing that any other male branches of his family had ever been similarly affected. The periodic discharge has continued since the year 1839, and for several years previous to this period he was a frequent sufferer from epistaxis and hæmoptisis.

N.B.—Lumbar pains always accompany the discharge.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of June 28; M. BRONGNIART in the Chair.

EXPERIMENTAL PHYSIOLOGY—FUNCTIONS OF THE SPINAL CHORD.—M. Magendie read, on this subject, a short paper, the principal object of which was to defend the opinions expressed by himself on the difference of function between the anterior and posterior divisions of the medulla spinalis. If, says M. Magendie, a pair of rachidian nerves be carefully laid bare, both roots are found to be endowed with sensibility, but in a very different manner. In the posterior, the origin of sensibility is in the spinal chord; in the anterior roots, the sensibility is propagated from the surface. Thus, when the anterior roots are divided, the distal portion only retains its sensibility, and loses it, also, when the posterior roots are divided in their turn. In these, on the contrary, the spinal extremity remains sensitive; whereas the distal portion is perfectly insensible. Therefore, sensation is propagated from the spinal chord through the posterior roots, and reflected back again to the spine through the anterior—a result already established in 1839 by M. Magendie, and now fully confirmed by further experiment. The posterior roots are constantly sensitive; but it sometimes happens that, when the dissection has been attended with considerable hæmorrhage, the anterior roots are found to be deprived of sensibility; after a few minutes, sensation is always restored—an interruption in the accomplishment of a function deserving of notice, and never to be observed in the posterior roots of the spinal nerves.

CONDITION OF THE BLOOD IN SCURVY.

M. Andral reported a case in which the analysis of the blood confirmed the results of the researches of MM. Becquerel and Rodiet, published in our last number. A man, aged sixty-one, had, for several years, suffered from the gradual progress of general debility. Numerous petechiæ and broad patches of ecchymosis existed in various parts of the body, blood flowed almost continually from the nares, the gums were tumefied, &c. When the patient was admitted into hospital he was labouring under pulmonary congestion and evident febrile excitement. A small quantity of blood was removed from the arm, and M. Andral embraced that opportunity of examining the chemical composition of the circulating fluid. The clot was small, but dense and covered with a thick fibrinous crust. The chemical analysis gave the following results:—Fibrin, 4.420; Globules, 44.400; solid elements of serum, 76.564;

water, 87.16. Diminution of the fibrin was not, therefore, a necessary condition of the existence of scurvy, but a secondary alteration referrible to the intensity or duration of the disease.

M. Magendie remarked that it was not impossible that the fibrin, although unchanged in its quantity, might have undergone in its composition modifications by which its conglomeration might be prevented. The same might likewise be observed with regard to the globules; hence the very great difficulty of drawing any important pathogenic conclusions from similar researches.

DISEASES OF THE LARYNX.—M. Segonet forwarded a memoir relative to the ossification of the laryngeal cartilages. From his researches the author was led to the conviction, that this ossification always begins in the neighbourhood of muscular attachments, is first observed in the cricoid, and lastly in the arytenoid, cartilages. When completely ossified, the cricoidian ring can no more be received under the thyroid cartilage, hence the impossibility of producing the higher notes from the chest.

ACADEMY OF MEDICINE.

Meeting of June 29; M. BEGIN in the Chair.

SPARKLING SYPHILIS.—A letter was read from M. Torvignot, in which that gentleman presented a new explanation of the singular phenomena observed in sparkling syphilis. The bright specks noticed in the eye are, in his opinion, the result of the presence in the humours of floating particles of the crystalline capsule, or of a morbid secretion of the same membrane.

OBSTRUCTION OF THE SPERMATIC TUBES.—M. Gosselin read an anatomical memoir on this subject. The vas deferens, the globus major and minor of the epididymis, the small seminiferous ducts of the testis, had all been found completely obliterated. In one instance only had the author found the vas deferens closed up. The vesicula seminalis was distended with fluid, but contained no spermatozoa. These animalcules were, on the contrary, found to exist in abundance in the testis. M. Gosselin was of opinion that these anatomical alterations were often not detected during life, and caused no morbid symptoms: in the first place, because the seminal secretion might be absorbed; and secondly, because, when the disease occupied the globus major of the epididymis, the great number of ducts prevented the circulation of semen from being interfered with in a material manner.

CHEMICAL RESEARCHES ON POISONING BY ARSENIC, BY PROFESSOR ORFILA. (SECOND PART.)

The illustrious Dean first examined the question of the extraction of arsenic from the remains of poisoned subjects. Two methods had been hitherto proposed: carbonization with sulphuric acid, and incineration with nitrate of potash. The Institute had preferred the former. The Academy of Medicine had placed both these methods on the same line. M. Orfila now proposed another mode of decomposition, viz., by chlorine in a gaseous state; the arsenic thus obtained was more abundant, and its characters better defined.

With regard to the possibility of the introduction of arsenic into bodies deposited in arse-nical soils, M. Orfila had made fresh experiments. Having obtained some earth from a cemetery in which the presence of arsenic had been positively ascertained, he had interred in it a full grown foetus, a human liver, and other remains; after three months' sojourn, it was impossible to detect in these organs the faintest trace of the metal.

Turning to the important question of antidotes, and particularly to the protochloride of tin, M. Orfila remarked that the Italian school, headed by Giacomini, was absolutely opposed to the exhibition of chemical antidotes. There was no doubt, however, that in poisoning by nitrate of silver, chloride of sodium was pre-eminently useful: after the ingestion of poisonous salts of mercury, copper, lead, &c., albuminous warm

water was evidently more efficient than warm water alone; and, in opposition with the Italian doctrines, it was clear that intoxication by salts of lead, or baryta, would be more properly met by the ingestion of a solution of sulphate of soda, than by mere aqueous draughts. The reactions were instantaneous, and took place in the stomach exactly as they would in a glass retort. As to the protochloride of tin—the antidote recommended by M. Proumet against corrosive sublimate—it was not easy to obtain, nor was its exhibition without disadvantages. It was not always easy to ascertain in a short time the exact nature of the poison which had been taken; and in any other intoxication but that produced by corrosive sublimate, the protochloride of tin would be injurious. An antidote, in order to be deserving of confidence, should present the following properties:—It should be a substance readily obtained, and innocent even when exhibited in large doses; it should act chemically on the poison, so as to form with the latter an inert compound, or at least a compound less injurious than the poison itself; further, an antidote should, in order to be eligible, tend to produce vomiting. In these various respects, albumen was particularly deserving of notice; it was always at hand, promoted sickness, and formed with mercurial salts a compound less injurious than these salts themselves. In fact, the salutary action of albumen, in cases of poisoning by mineral substances and acids, was such that the following precept would, doubtless, be universally admitted. In all cases of poisoning, even before the nature of the poison had been clearly ascertained, it was proper to exhibit tepid albuminous water, because it was easily obtained, promoted sickness, diminished the toxic action of numerous mineral substances, and, at any rate, was never injurious.

LITHOTOMY AND LITHOTRITY. (ADJOURNED DEBATE.)

M. Roux stated, that one of the patients whom he had operated for stone (see our last communication) had died, since the last meeting of the academy, from the progress of collapse.

M. Civiale endeavoured, in a long speech, to defend the method of crushing vesical calculi from the imputations which had been brought against it. Without entering on this occasion into the question of statistical results, M. Civiale endeavoured to establish the superiority of lithotripsy over cystotomy, and stated that many of the unfortunate results observed in consequence of the application of the former mode of operation were referrible in a great measure to the inability of the surgeon or to the errors of diagnosis, by which patients to whom lithotripsy was inapplicable, from the volume of the concretion, or other circumstances, had still been submitted to the process.

Meeting adjourned at five o'clock P.M.

INTERMITTENT FEVER AND THORACIC AFFECTIONS.—We have already, on various occasions, had opportunity of speaking of the alleged antagonism of phthisis and ague. The question does not yet appear to be decided: *a priori*, it would not be unreasonable to admit that the liver and lungs performing the same functions by different means, viz., the separation of carbon and hydrogen from the blood, the vital activity and, consequently, the frequency of disease in the respiratory viscera must be in inverse ratio with the vitality and frequency of morbid manifestations in the chylo-poietic organs. This is, no doubt, correct; and we find in India, for instance, a contrast between hepatic and pulmonary affections. With regard to the intermittent fever, the same chain of reasoning cannot be adopted. The spleen, the organ constantly diseased—a mere *diverticulum sanguinis*—does not perform any function which can be compared with that of the lung and liver, and as it affords no physiological we do not well see why it should present a pathological contrast with the organs contained in the chest. Statistical returns have, indeed, hitherto been unfavourable to the alleged antagonism of tubercular disease and ague; M. Salvagnoli now publishes, however, in the "An-

nali Universali," numerical statements which have a contrary tendency. The province of Grosseto contains a population of from 75,000 to 80,000 souls, from the year 1840 to 1846, exclusively. It may, therefore, be represented by 461,995. 149,673 individuals were during that space of time affected with various diseases, &c.; 65,870 (nearly one half of the whole) were attacked with intermittent fever; only 227 cases of tubercular consumption, and 242 of scrofula, were observed; cancer was noticed in sixty one instances; but acute diseases of the lung were observed in 11,482 patients.

THE MEDICAL BILL.—The new bill has received the sanction of the Chamber of Peers, and has only satisfied partly the friends of medical reform. The abolition of the second order of practitioners is a measure which has long been called for, and which is established by the bill; it does away with the election of professors by competition, and we would regret deeply that this guarantee should be removed from the professorship. We are well aware of the nature of the objections which can be raised against the institution, but we do not consider the "Chambre des Pairs" competent to decide in the matter. It must be acknowledged that, after a competition, the nomination of the most deserving is not always certain to take place. But still that mode of election excludes mediocrity. One of the most serious arguments against the institution of public competition for chairs is certainly the excessive labour of a barren and unprofitable nature which it renders necessary, and to that degree that the successful candidate is often incapacitated from any future exertion. Perhaps it is to the *concours* that we must attribute the following singular fact to be referrible, viz., the Faculty of Medicine of Paris is composed of professors, each of undoubted and several of transcendent merit; but still the faculty, as a body, takes but little share in the progress of science. Amussat, Louis, Joubert, Rayer, do not belong to the School of Medicine; Lisfranc had been rejected; and Gendrin was unsuccessful in the only contest he ever was engaged in. Another point on which we believe the judgment of the Chamber of Peers to have been misled, is the free permission granted to nunneries and clergymen to give gratuitous assistance in the shape of advice and medicine. Now, we believe that it is only the members of the medical profession who ought to have the right to give gratuitous assistance and advice, because they alone can do so judiciously. No respectable practitioner ever refused his assistance to the poor, and many have injured their own health and prospects by continual sacrifices of their time and money. To be of service as a medical adviser, the will alone is not sufficient, and the dispensing nunneries of Paris, with the best intentions, often commit most uncharitable acts of gratuitous surgery. We have seen cases of gonorrhoeal ophthalmia treated by most excellent but most ignorant nuns, and terminating in the loss of both eyes; we have seen an amputation of the arm rendered necessary by maltreatment of a whitlow, &c. Fortunately the bill has not yet passed through the narrow gates of the Chamber of Deputies, where, we have no doubt, many of these errors will be corrected; and the recent return of M. Maligne for the fourth arrondissement of Paris permits us to hope that liberal ideas and intelligent measures will at last prevail.

TANIA SOLIUM.—ETHEREAL OIL OF FERN.

In answer to the inquiries of a correspondent, we will say that in the case of tania, related in our communication of June 12, the eth. oil of fern was exhibited in pills; 72 drops divided into 12: six taken in the morning and six in the evening. Two hours after the ingestion of the last pill, one ounce and a half of castor oil was also given, for the purpose of hastening the action of the pills.

In the case which has fallen under the observation of our correspondent, various remedies, and even the oil of fern, have been used, and unsuccessfully. In Paris, also, the ethereal oil, pre-

pared from the buds (*bourgeon*) of the male fern, is generally *inert*; but the oil extracted at Geneva, from buds collected in the mountains, is as constantly efficient. In the neighbourhood of the Lake of Geneva, tania is an extremely common disorder; and there the ethereal oil has superseded all other methods of treatment. One dose is usually sufficient. We would, therefore, recommend our correspondent to endeavour to obtain some of the oil from Geneva, where it is not only extracted from the buds, but also from the root. M. Guibourt, of Paris, receives it directly from Geneva, and an application to him would be immediately attended to.

D. MCCARTHY, D.M.P.

Symptoms which followed the Ingestion of Large Doses of Quinine in the Stomach of Dogs.—The experiments were performed by Dr. W. C. Baldwin, of Montgomery, Alabama, U. S., and yielded the following results:—Restlessness generally preceded all other symptoms, as was indicated by the animal changing its position often, and constantly moving from place to place; vomiting, or, when the oesophagus was tied, efforts to vomit, succeeded; purging was noticed occasionally, but in no instance except when the medicine was taken by the stomach; then came on a muscular agitation, with a constant motion of the head. In attempting to walk, the dog would totter from side to side and fall, or, if he maintained his feet, would walk in a direction different from the one which he seemed to desire. When under the full operation of the poison, the power of moving or standing was lost, and the extremities seemed paralyzed. The pulse rose from 110 to 160, and in one instance even as high as 240, per minute; great oppression of breathing was present, and sometimes frothing at the mouth; dyspnoea excessive, sometimes panting, at others slow and laboured; countenance expressive of great anxiety; the pupils of the eyes were invariably dilated, and generally to an enormous extent, leaving but a small ring of the iris perceptible, and vision seemed entirely lost; convulsions were observed in every case except one; furious delirium was present in one case, as was manifested by the dog barking and biting at everything about him; sometimes a profound coma would ensue, accompanied with slight muscular agitation, slow and heavy breathing, terminating in death in a very few minutes after the poison had been taken. Its effects upon puppies seemed to be proportionally much greater than upon dogs fully grown.

Secretion of Tears in Infants.—Very young infants never shed tears when they cry. When once this secretion is established, it may cease during the course of a disease, and children then cry without shedding any tears. Trousseau regards this circumstance, when it occurs, as one of bad omen.

The best Mode of administering Quinine.—Its poisonous effects, says Dr. Baldwin, may generally be avoided by proper attention to the mode of administration. Of all the forms of giving it, that of the pills seems most objectionable, as they may become entangled in flakes of mucus, and pass off undissolved, or, meeting with some obstruction, may be retained. A large quantity may in this way collect, until, suddenly meeting with a solvent, its whole force is spent upon the system at once, and then causes serious mischief. Solution by some acid, and largely diluted with water, possesses a most decided preference over every other mode, and in this way be given in heroic doses, at one, two, or three hours' intervals, and persisted in with safety.

Poisonous Effects of Sulphate of Quinine.—Dr. Baldwin relates in "The American Journal of Medical Sciences" some cases where the exhibition of this medicine was followed by blindness, convulsions, and death; and remarks, "From all that I can gather, I am disposed to think from fifty to eighty grains of a pure article of quinine, given in solution at one dose, will produce death nine times out of ten, in healthy adults, and occasionally even smaller quantities. How far

its operation may be modified by morbid action is a matter for consideration at the bedside."

Fracture of the Spine.—Dr. Harrison relates the case of a man, thirty-three years of age, of intemperate habits, admitted into the Cincinnati Hospital, in consequence of having fallen into a sawpit, while in a state of intoxication, and was there found cold, senseless, and nearly dead. There was no external contusion—no apparent injury to the spine. There was distention of bladder from urine, the bronchii were filled with mucus, and the expectoration difficult. The stools were involuntary. Cold applications were applied to the head, external warmth to the body, and diffusible stimuli administered internally. There was entire paralysis of motion and sensation from about the middle of the dorsal vertebrae around the body; the lower half of the trunk and the inferior extremities were insensible and motionless. Five days after the accident, bed-sores about the hips made their appearance, and in a fortnight he died, extensive sloughing having occurred in the soft parts covering the sacrum and hips; the delirium, three days before his death, having greatly increased. The post-mortem examination revealed the following appearances:—The fifth and sixth dorsal vertebra, through its body, was fractured, with but little displacement of the fractured parts. The spinal cord was apparently uninjured; the kidneys were softened and ulcerated; the bladder was thickened, and the internal coat abraded of its mucous tissue, purulent matter adhering to it. The case is one of singular interest, from several considerations. First, the fractured dorsal vertebra was not detected till after death, though the symptoms pointed most significantly to such a lesion. The paraplegia, the character of the respiration, and the tendency to gangrene, so early exhibited in consequence of the decubitus, were pointedly evincive of such a grave lesion. Secondly, the complication of the more profound pathological state of the spinal marrow with a strong proclivity towards temulent mania, arising from the previous and long-indulged habit of spirituous potations. And, lastly, the lesion of the kidneys, and of the bladder, no doubt consecutive and dependent upon the loss of innervation occasioned by the state of the spinal column. The molecular integrity of the cord was evidently most seriously deranged; this may have partaken essentially of the nature of a contusion, destructive to its vitality, without any very signal proofs of structural alteration.

Rupture of the Extensor Tendon of the Leg.—Dr. G. C. Blackman, of Newburg, Orange County, N. Y., relates the case of an old lady, sixty years of age, who, in endeavouring to avoid coming in contact with her daughter at the top of the stairs, fell, her right foot remaining fixed while the whole weight of the body was thrown backwards. When lifted up she could not raise her leg. She stated that, when leaning her head against the wall, she could move the whole limb freely, so far as rotation was concerned, but could not lift the leg in an upward direction. The patella was loose, and admitted of extensive lateral motion. There was considerable uncasiness in the region of the knee. A physician was called in, who thought the old lady a little nervous, and prescribed accordingly. Three months afterwards, Dr. Blackman was called in, who, upon examining the knee, found a considerable depression just above the patella, which the patient thought less than it was shortly after the accident, the motions of the patella also less. A straight concave splint was applied with a pad over the knee, to approximate the divided ends. This was worn with decided benefit for a month, and she could raise her leg from the chair several inches. She afterwards placed herself under the care of a "natural bone-setter," who, treating it as a dislocated hip-joint, employed severe manipulations, and, in consequence, produced severe pain, and prevented her from walking but very little, which is only accomplished by the aid of a crutch.

Malformation of the Penis.—This occurred in a child, which was first brought, under surgical

treatment when eight months old. The penis bore a striking resemblance to the clitoris, being imbedded in an oval depression in the adipose substance covering the pubis, beyond the level of which it did not protrude. Throughout the whole length of its inferior border it was united to the scrotum, the surface of which was constantly irritated and excoriated by the urine, which escaped from a very small opening close to the junction of the parts. The prepuce was ample, but the glans, so far as it could be detected, appeared to be very small. Whether the latter was imperforate or not, it was difficult to say, though hypospadias was suspected. The cure was effected by the following operation:—A small sound was introduced into the urethra, and, while the penis was elongated as much as possible, that portion of the apex beneath the bridle was divided, after which the dissection was continued through the skin and cellular substance in a semilunar direction on each side of the penis, embracing about two-thirds of the circumference of this organ. Following the urethra, the lower border of which was necessarily exposed, a cut was made in the direction of the canal for nearly an inch. The glans was then found to be imperforate, the urethra terminating just behind. A transverse incision through the integuments on each side of the penis was then made, commencing at the upper extremities of those which had previously been made in a lateral direction; and the portions thus detached were drawn together by several sutures, and united in the median line under the penis. A small leaden tube was then introduced into the urethra, and the penis was thrust into the finger of a glove of a suitable size, which was fastened with tapes around the body. In a month the wounds had healed, and no contraction had taken place.

Case of Hydrops Pericardii suddenly formed.—Dr. S. Jackson, of Philadelphia, United States, was called to a lady in a dying state, who had been delivered of her first child six hours previously, after a severe labour. The placenta did not come away by the natural efforts; and upon introducing the hand, after waiting several hours, there was found an hour-glass contraction, to overcome which, considerable exertion was used. After this she appeared to be going on well, complaining only of drowsiness and some little debility. She then became suddenly pale and faint, and in a short time expired. Upon a post-mortem examination, the uterus was found well contracted and perfectly normal; the abdomen and its viscera entirely sound; the cut muscles looked very pale; the pericardium contained two quarts of water, almost limpid; no inflammation in the organ. The lungs were perfectly healthy. This effusion could not have existed in any appreciable degree in the morning, for the patient had walked up a long staircase, and had gone through a painful labour without any anhelation. This case, says Dr. Jackson, appears to be analogous to those suddenly-formed hydroceles which are sometimes met with in practice.

Tubercles in the Pericardium, Vena Cava, Columnæ Carnæ, &c.—Dr. J. D. Task, of Brooklyn, New York, attended a negro boy, fifteen years of age, who had frequently suffered for several months with palpitation of the heart, pain in the head, with drowsiness and unwillingness to exert himself. No profuse taint had ever been noticed in his family. About a month before his death he was laid up, complaining of pain in the foot and knee, cough, and dyspnoea, which, till the close of his life, prevented his assuming a recumbent position. Expectoration of a green tenacious mucus; diarrhoea for two or three days before death; partially comatose, during the last twelve hours; at no time was there any disturbance from light or sound. On examining the body after death, the dura mater was found adherent to the arachnoid by numerous points and patches along the whole course of the longitudinal sinuses. No tubercles in the meninges or substance. The pleura of both lungs adherent almost throughout, except the

anterior portion of the right, in the cavity of which there was a pint of serum. The trachea, œsophagus, and base of the heart consolidated into one mass, by adhesions formed between bronchial glands that were immensely hypertrophied, and filled with tuberculous matter. Both lungs loaded with tubercles; the superficial portions of each much congested. The large bronchial tubes, as far as observed, all filled with green tenacious mucus, so as completely to destroy the functions of the lungs. The pericardium and surface of the heart, after removal from the body, presented extensive deposits of tubercles, which increased in size and in number from the apex to the base. Here the subserous cellular tissue was almost entirely occupied by them, especially that below the portion of pericardium which is reflected for some distance over the origin of the blood-vessels. The anterior surface of the heart presented very considerable roughness from effusion of lymph, as well as from tubercles which occurred in isolated granules. The diaphragm loaded with tuberculous matter infiltrated among the muscular fibres, and there were similar deposits in the muscular structure of the œsophagus. There was a tubercle two lines in diameter upon one of the columnæ carneæ, and another of about the same size in the descending cava at its junction with the vena innominata of the left side. Fibrous polypi, firm and large, among the meshes of the chordæ tendinæ of the right ventricle, and others in the aorta at the seat of its valves, and at the mouth of the pulmonary veins, extending some distance along the vessels. These, under the microscope, presented no trace of vessels, so that their formation could not have preceded death for any considerable time. Serum in the abdominal cavity, and tubercles the size of a pea in the liver.

On Letting Blood from the Jugular in Diseases of Children.—"I would," says Dr. Chas. Hildreth, of Zanesville, Ohio, U.S., "make this operation the rule, instead of the exception, in many of the acute affections of children under two or three years of age. The following method, in order to fix the head and chest immovably, I have found to answer effectually, and to be very convenient in practice. The nurse having exposed the right shoulder of the child, and seated herself on a low chair, and, in holding the child across her knees, carefully confines the arms. The surgeon, seated at her side, receives and secures its head between his knees. With the thumb of the left hand he now compresses the jugular where it crosses the first rib; while the remaining part of the same hand is employed in fixing the chest of the child against the nurse. With the right hand the operator makes a free opening into the vein with whatever form of lancet he is accustomed to use. The blood is received into a cup, the edge of which, applied a little below the orifice, likewise serves to compress the vein. From a robust child blood escapes with astonishing rapidity, particularly when the child cries or struggles. The quantity of blood desired having been lost, a compress is applied to the orifice, and the pressure taken off the vein below. After the child becomes quiet, the compress is removed, and the wound is closed by a piece of adhesive plaster. The bandage and compress usually advised is very objectionable, as it not only obstructs the free return of blood from the head, but its presence irritates the patient. In clearly marked acute inflammations of the brain and its membranes, lungs, pleura, and trachea, accompanied by high fever, the bold and rapid abstraction of blood from the jugular is preferable to the use of leeches, &c."

Anatomical Anomaly.—Dr. Samuel Parkman, demonstrator of anatomy, medical department, Harvard University, states that, while examining a subject with a remarkably well-developed muscular system, he noticed the following anomaly, which is not without practical importance. It is well known to anatomists that it is not uncommon to find traversing the axilla a muscular band, extending from the external border of the latissimus dorsi muscle to the cor-

responding one of the pectoralis major. In the case in question, the strip was about one inch and a half in length, and the size of the little finger; it left the latissimus at the point where its muscular fibres cease and the tendinous commencement, and was attached to the pectoralis tendon just at its humeral insertion. Consequently, the bundle composed of the artery surrounded by the brachial nerves, where it lay between the anterior and posterior tendons, just as it emerges from the axilla, and where we should select to tie it in case of need, was crossed by a muscular bridge, lying between it and the fascia and integuments. Such a band would, of course, require division before the artery could be attained, and might seriously embarrass an operator who was not prepared for it. The anomaly existed on both sides. Maligne, in his "Surgical Economy," mentions that, while demonstrating to his class the ligatures of the arteries, he encountered a muscular band, which he at first took for the coraco-brachialis muscle, but recognised his error by not finding the nerves, &c., to its side. This evidently was a different condition from the above, probably a variety of the usual anomaly; he has neglected to mention exactly what it was.

Effects of Mercury on Children.—Dr. John B. Beck shows, in an interesting paper, that children are salivated with great difficulty, and that, notwithstanding this, the effects of it are frequently more energetic and uncertain than they are in the adult. And, taking these as the basis, he makes the following remarks:—1. If salivation occurs so rarely in children under a certain age, then it is evident that it can never be made a criterion by which to judge of its influence on their systems. To attempt, therefore, to produce this effect, as we do in adults, is manifestly improper. 2. The fact that mercury may prostrate and destroy a young child, even though it does not cause salivation, it is to be feared is not sufficiently appreciated. A simple dose of calomel, though large, may be well borne by children of ordinary strength of constitution, yet even this is not entirely safe in all cases. 3. The use of mercury in young subjects, as an alterative, should in all cases be conducted with great caution. 4. Great care should be exercised in ascertaining, as far as possible, constitutional peculiarities. Whenever parents show indications of scrofula, or where there is a hereditary predisposition to consumption, great caution ought to be exercised in the use of mercury in their offspring. 5. It should be exhibited with great caution when a child has been sick for a considerable length of time, and when the strength has been very much reduced. In this state of constitutional depression, a single cathartic dose of calomel sometimes proves fatal. 6. The too common practice of giving calomel as an ordinary purge, on all occasions, is certainly unjustifiable. In a great majority of cases milder cathartics are decidedly to be preferred.

Vicarious Menstruation from an Ulcer in the Right Mammary.—The patient was a girl, twenty years of age, under the care of Dr. E. C. Barker, of Abbeville, U. S., who had been suffering for a length of time from an affection of the breast, supposed to be cancer. The patient was anemic and chlorotic, and presented the usual symptoms attendant on those conditions. Had never menstruated regularly or freely, and for the last six months nothing but a thin, pale-yellowish, gloiry discharge took place at each monthly period, sometimes slightly coloured with blood. The breast was more perfectly developed than could have been expected from her general appearance; was somewhat flaccid; the nipple prominent, the superficial veins running to it larger and more tortuous than natural; the whole having the appearance of a mother's breast from which the milk had just been drawn. She said it was sometimes larger than at others. About a quarter of an inch from the outer edge of the areola, and immediately under the nipple, was an ulcer with slightly elevated edges, measuring across the base 1½ inch, with an opening in the centre a quarter of an inch in diameter, covered with a thin scab,

which on being removed, and a gentle pressure applied, a few drops of thick muco-purulent matter were discharged, not very offensive to the smell. The ulcer appeared to be of an indolent fistulous nature, with callous edges, the size of a hen's egg, not painful to the touch, and slightly movable. A probe passed upwards and backwards 2½ inches, terminating in a *cul de sac*. It was stated that every month the breast enlarged, the ulcer inflamed, and a discharge of sanious purulent matter took place, which lasted for a few days and then dried up. At these times she suffered from giddiness, severe pains in the lower parts of the abdomen, and sickness of stomach. The ulcer was produced by the point of a leaf of palmetto-royal piercing her breast while stooping forwards, about the time the menses were making their appearance; since then she has been very irregular, with but little discharge from the uterus. The ulcer was injected twice a day with warm water, in which was a small quantity of Castile soap, and dressing of cerate afterwards applied to it, the bowels being kept regular with, occasionally, doses of calomel and colocynth, with frictions to the spine; afterwards syrup of iodide of iron was given. This treatment was continued for six months, the health generally improving; the uterine discharge gradually increasing in quantity, and becoming more natural in quality. The ulcer was finally dressed with a lotion containing three grains of iodine, twelve grains of chloride of soda in a pint of water, twice a day, when it gradually healed, and the induration disappeared.

Empyema, in which the Operation for Paracentesis Thoracis failed from a Cause not generally noticed.—Dr. J. A. Sweet, New York, mentions the cause of failure in evacuating the pus in this case was the existence of a false membrane lining the pleura costalis, and so loosely attached to it as to be pushed before the point of the instrument, so that the cavity containing the pus was not opened. The possibility of this source of failure is important to be borne in mind, and its occurrence should be guarded against by using a very sharp instrument.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

J. M. ARNOTT, Esq., F.R.S., President.

ON THE INFLAMMATORY DISEASES OF THE KIDNEY.

By George Johnson, M.D.,

Medical Tutor in King's College, and Physician to the Public Dispensary, Lincoln's-inn. [Presented by R. B. Todd, M.D., F.R.S., &c.]

The author arranged the inflammatory disease of the kidney into two classes: the first class including those diseases which result from some local cause, such as the mechanical irritation of a calculus, &c.; and the second class including the diseases which originate in some abnormal condition of the blood. The present communication refers to the latter class only. The form of disease first treated of was that which occurs in connection with scarlatina. The anatomical changes occur chiefly in the convoluted portions of the urinary tubes, and consist in an abundant formation of epithelial cells. The Malpighian bodies and the straight tubes of the pyramids are primarily unaffected. The author proposed to call this form of disease "acute desquamative nephritis," the reported cases of the same form of disease occurring unconnected with scarlatina. He next spoke of the same disease occurring in a chronic form—"chronic desquamative nephritis." He described minutely the changes which the epithelial cells and the tubes undergo, and mentioned several facts which appear to him abundantly sufficient to prove that the cysts which are often observed in these cases are dilatations of the basement membrane of the tubes. The anatomy of this form of disease affords a satisfactory explanation of two remarkable phenomena:—1st, the great wasting and contraction of the kidney; and 2nd, the copious secretion of pale urine, of low specific gravity, which is frequently observed

in these cases. The author next spoke of the condition of kidney produced by such substances as oil of turpentine or cantharides. In these cases the irritation appears to be confined to the Malpighian bodies, and produces hemorrhage from their delicate vessels. The epithelial cells of the tubes are unaffected, and the author proposes the term "hemorrhagic nephritis," to distinguish this form of disease from cases of "desquamative nephritis." The disease next spoken of was "suppurative nephritis." The author reported a case in which this disease appeared to have been produced by an unhealthy carbuncular inflammation of the cellular tissue of the neck being determined to the kidneys by the imtemperate use of alcoholic drinks. The author then spoke of fatty degeneration of the kidney, and described two forms of the disease, the one being simple fatty degeneration, and the other being complicated with a nephritic condition. All the forms of disease alluded to may be detected and distinguished with ease and certainty by a microscopical examination of the urine; and the information thus acquired is of as much importance, with reference to prognosis and treatment, as any information derived from a physical examination of the chest in cases of pulmonary and cardiac disease. The author gave directions as to the best mode of making a microscopical examination of the urine, and concluded by some observations tending to show the inutility and danger of administering diuretic medicines in most cases of renal disease.

ON SUBACUTE INFLAMMATION OF THE KIDNEY.

By John Simon, F.R.S.,

Assistant-Surgeon to King's College Hospital, and Demonstrator of Anatomy in King's College, London.

The chief points in Mr. Simon's paper were the following:—He first gave an exact definition of the nature of glandular inflammation generally, showing how often no interstitial deposit of organizable material attends it, and, on the contrary, how much more constantly it evinces itself in modifying the physical properties of the secretion, by admixture of albuminous material, or otherwise. He stated, that in the more complicated glands, many of the most obvious structural changes followed, and were caused by the lowest amount of inflammatory action; the secretion becoming first disordered, and then reacting, often mechanically, on the structure of the organ. He illustrated this in the kidney, showing its subacute inflammation to commence as an epithelial disease, and to produce the final destruction of the organ, in a great degree, mechanically. After citing the causes of the disease (among which he mentioned various fevers besides scarlatina), he proceeded to describe the overabundant formation of modified epithelium, which is the first stage of the disease; stating that the tubes were bunged by it so as to be totally impervious, and were often so distended that their liminary membrane would give way, and suffer its contents to be effused amid the surrounding blood-vessels. The microscopical examination of the urine would often show the specific cause of the disease—biliary matter, or oxalate of lime, or lithic acid, or fat, entangled or included by those well-known fibrous casts of the tubules discovered by Dr. Franz Simon. These casts, and the more or less modified epithelium, were signs of renal irritation simply, the specific diagnosis being in each case furnished by additional matters which accompany their escape. He described the final shrinking and atrophy of the kidney as dependent on the gradual absorption of spoiled tissues—not to the contraction of effused lymph; and explained away the appearances which had led many observers to ascribe an unreal influence to the latter cause. He reviewed the subject of "Bright's disease," and stated his opinion, that, in all instances of disease to which that name is applied, subacute inflammation plays an important part, and produces its characteristic symptoms. It had appeared to him, that this inflammation was always grafted on the fatty degeneration,

so well described by Dr. Johnson. He recommended that the name of "Bright's disease" should be discontinued; that the term "scrofulous degeneration" should be used for one form, and the common one of inflammation for the other. The former had not appeared to him to lead to contraction of the kidney, which he had found mainly in the other class of cases. In tracing the inflammatory changes, he gave an account of the formation of renal cysts, believing their development to be an almost essential part of the inflammatory process; his theory of them being, that, when the tubes have been ruptured, these cysts are developed from the effused epithelial germs which (by the destruction of the liminary membrane) are brought into unnatural circumstances. They had appeared to him an extravagant overgrowth of common nucleated cells, down to the size of which he had repeatedly traced them. From this remarkable smallness in which they commence, it seemed impossible that they could arise from the tubes; nor had he ever seen any such connection. In a few remarks on treatment, he expressed a strong opinion against diuretics, and much reliance in the sweating-bath. He spoke of the disease as one of almost incredible frequency, and said, that in a vast majority of cases the disease had been overlooked during life, while its traces in the dead body were such as might easily elude observation.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Agarston Carfrae, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

A Medical Pupil.—Glycerine is prepared in the following manner:—Digest equal parts of ground litharge and olive-oil in a little boiling water, stirring and keeping up the water as it evaporates. When of the consistence of a plaister, wash it well with hot water; decant the latter, and filter; pass sulphuretted hydrogen to throw down the lead, and then filter, and evaporate to a syrup in a water-bath.

A College Member, of thirty years' standing.—The Registration Bill would perpetuate the abuses of the College of Surgeons, and would afford no guarantee to the profession of a more rigid examination for the diploma.

Mr. T. Savory.—The amount of the bill can be recovered in the County Court, with but little trouble and expense.

Galen.—The letter was written by Mr. Thomas Wakley, and addressed to himself. We wish that his suggestion may be speedily carried into execution.

A Candidate.—The work is not held in much repute. We would advise our correspondent to frequent the dissecting-room, and acquire his knowledge by a diligent use of the scalpel.

Beta.—Most of the continental universities require residence, in order for the candidate to obtain a degree. Giessen, we believe, has now given up selling its diploma without requiring an examination. Its possession confers no privileges.

An Inquirer.—The vicarious discharge seldom resembles the healthy function, although cases are recorded where the menstrual period has been exactly observed. The work is published by Hightley, Fleet-street.

M.D., Liverpool.—The fee cannot be recovered unless there be some proof of a contract to pay. The loss had better be quietly sustained.

A Bristolian.—We have no space for the communication, and at the present time the subject has lost much of its interest.

A Young Navy Surgeon.—The matter is under discussion. If he were to lay his case before Sir William Burnett, we have no doubt he would give it

every attention, and would probably help our correspondent out of his difficulty.

An Invalid.—1. The insurance-office is bound to pay. 2. A medical examination is necessary, and according to the report will be the decision of the office. 3. It is a respectable concern. 4. The medical gentleman is certainly entitled to his fee, which ought to be promptly handed over to him.

An Edinburgh M.D.—There will be no difficulty in procuring an examination at the London College of Physicians, which is necessary, if our correspondent thinks of practising in London.

A Retired Practitioner will find the general subject of his note anticipated. We will publish the case of *endo-pericarditis* at an early opportunity.

J. B. C., City.—The nuisance of which our correspondent complains ought immediately to be removed. It must be a prolific source of disease. The City authorities ought to be memorialized. The graveyard nuisances are sources of profit to those who are placing obstacles in the way of their removal. The facts stated should be made public. We only want the permission of our correspondent to do so.

A Subscriber and Occasional Correspondent.—The papers have not yet been received. The suggestion shall be attended to.

Mr. Banks is thanked for his communication. It will appear in an early number.

A Looker-on.—The case of "bungling operation" cannot be published without being authenticated. It is a much easier part to look on than to operate.

Senex.—There is some doubt as regards the efficacy of the test. Consult the volume mentioned, and seek the assistance of some practical chemist.

An Assistant.—An advertisement in the Medical Times, or an application to some respectable medical agent, is the best way which can be adopted.

Dr. Ryott's communication has been received.

Mr. Brooks.—We will make the inquiry, and transmit a private note.

A Dublin Surgeon.—The work is now complete, and can be had of any bookseller.

Mr. H. J. Browne, Paington.—The work is a valuable addition to the library, and is published by Longman and Co; also, Rees and Churchill.

J. J. M.—The book debts can be legally recovered, if within the statute of limitation.

A. Z.—The general rule is to pay, in a manner agreed upon, the average of one year's income. Great circumspection is required.

Mr. Smith's communication can only be inserted as an advertisement.

M.R.C.S., London.—Application must be made to Sir W. Burnett, Director-General of the Medical Department of the Navy. The qualifications, we think, will do.

A Surgeon, who informs us that he is desirous of joining the National Institute, had better address Mr. Ross, Hanover-square.

Letters and communications have also been received from Mr. R. N. West, Lincolnshire; A Subscriber and Occasional Correspondent; Mr. Banks; A Looker-on; Senex; An Assistant; Dr. Ryott; Mr. Brooks; A Dublin Surgeon; Mr. H. J. Browne, Paington; J. J. M.; A. Z.; Mr. Smith; M.R.C.S., London; A Surgeon; J. B. L., City; A Retired Practitioner; An Edinburgh M.D.; An Invalid; A Young Navy Surgeon; A Bristolian; M.D., Liverpool; An Inquirer; Beta; A Candidate; Galen; Mr. T. Savory; A College Member, of Thirty Years' Standing; A Medical Pupil.

Dr. Guy, on his New Test for Arsenic, in our next.

strike at the heart of so many of our medical brethren, we can offer them the consolatory reflection, that whatever the position of our profession now, it is one that must hourly improve. Slowly, perhaps, but surely, our time is coming. The flood-tide of social improvement so fast and widely-spreading bears on its beneficent bosom the ark, alike of our augmenting appreciation and utility. The coming age will be as emphatically ours as its predecessors were those of war or religion. Just as their gorgeous pageantries fade into the ceremonies of life does our profession vindicate the realities of improved social existence. As they sink—a name in history—we rise—a potency in action. The depression of a thousand bad agencies, the neglect and contumely of fifty centuries of ignorance, disappear with the advance of that civilization to which, once placed in our true position, we are destined to be the surest heralds—the wisest aids and best guarantee!

Civilization is not a mere matter of abstract information, still less is it the highest kind of information if limited to a section of the community. It is an affair of conduct, more even than of science—of truths applied more than of truths discovered. The Greece that produced Solon was less informed than that which mirrored every ignominy and weakness of the Asiatics in the time of the Cæsars; yet how different the quality of the two ages, and how dissimilar the elements and hopes of a real civilization! The true basis of amelioration is a sound and widely-diffused knowledge, in which the heart participates as fully as the brain, and which, forming a practical use rather than an amusing luxury, is a matter of character more even than of memory or understanding. It is the union of the Athenian's knowledge, to the Lacedæmonian's doing, of what, in the largest sense, is right. It is not the existence but the royalty of Science that makes the only true civilization.

Now it is our distinction and hope that, to secure this kind of larger practical amelioration, society must look mainly to us. Our range of duty being the whole organization of man in health as in disease—psychically as well as physically—we alone offer that wider field of new action that an advanced society now requires. All that gives happiness, estranges pain, prevents disease, lengthens life, betters the individual, or improves the race—these, the greatest concerns of living humanity, and carrying with them the principal morals of society, belong to our care. On them we are the only teachers that can speak with authority, or that will by-and-by be listened to with conviction. We alone can make theory on them give way to demonstration, speculation to ascertained fact, doubt to certitude; and outside our pale there is no teaching nor knowledge that is secular beyond what forms a fraudulent empiricism on one side, and a perilous credulity on the other.

The neglected science of practical ethics—abandoned by the clergyman for the more seductive controversies of speculative faith—must be ours. It will be less his mission than that of the physician to undo uncleanness, indolence, bad temper, profligacy, hate, avarice, and intemperance. He is the man who, in the nineteenth century, will have to preach down—in every relation, domestic, mercantile, or public—the insane luxuries of lords, the mischievous or sordid prejudices of burghesses, and the fatal excesses of serfs, and to inspire through all classes and persons a healthful, a moderate, and fertilizing activity: for we are alone the people

who to the remote teachings of verbal revelation can add the visible, the proximate sanctions of natural religion—sanctions that blaze out as from another Mount Sinai in those striking facts of physiology that admit neither dubitation nor dispute. While far from displacing the sacred functions of the priest, it is yet our mission to piece out his imperfections, and add force to his contested authority. In fine, it is the great tendency of the age to give us, and it is our duty to be prepared to accept, the whole ministering of public health and its dependencies; and to perform our part of the responsibility, and lead the way to that desirable improvement, we shall touch in successive articles of this journal on the physiological ethics applicable to the different social classes.

It is a droll fact, sadly confirmatory of the opinion we have expressed on the non-identity of knowledge and civilization, that there is no section of our fellow-citizens more in need of whatever medicine can do for them in the way of ethical improvement than that of our wealthiest and best-bred aristocracy. The extent of their means is the very measure of their perversion; and there is no more active instrument in the misuse than the items of their information.

To offer with the Roman emperors rewards for new pleasure—which are almost uniformly new wrongs to nature—is the epitome of a great portion of their existence; and as if to illustrate the great natural law, that all happiness is usefulness, the absorbing passion of their lives—enjoyment—although aided by ample means and incessant attention, is less gratified than is, probably, any other portion of the community! If we take up the case of the woman of fashion—viewing her in the relations of wife, mother, and citizen;—but the illustration is too worthy in itself of a complete article to be broached at the far-end of this. We shall discuss it, then, in our next.

ASSISTANT-SURGEONS OF THE ROYAL NAVY.

We last week directed the attention of our readers to the neglect which the members of the medical profession in the army—a body of gentlemen whose education entitles them to respect, and whose services to honour—experience from the Government. The other meritorious officers of the army are about to be rewarded with stars and ribbons, those pretty toys which are pleasing to every one, yet the medical profession in this service is to be passed over in silence; and we suppose that to some other Administration than the present will be awarded the praise of doing justice to their medical servants. We have heard of no remonstrance from them to their rulers, and we were at first struck with astonishment that men, whose intelligence, honour, and courage were never questioned, should so quietly submit to be contemptuously treated. There may be two causes, however, which either singly or unitedly have prevented them from offering a respectful memorial to the Government: the one is a very deep sense of the injustice practised towards them, and the other an exalted state of mind which leads them to hold with a light hand those rewards which consist in the bestowment of an empty title or of a brilliant toy. Their avocations, perhaps, of all others, would lead them thus to feel, though we can hardly imagine that Philosophy has yet attained such an authority over the minds of her children as to make them entirely regardless of things which, though

THE MEDICAL TIMES.

SATURDAY, JULY 10, 1847.

THE MEDICAL PROFESSION AND THE FUTURE—ITS POWER OVER MORALS.

AMID the miseries of all kinds—privations domestic, anxieties professional—that each day

possessing no inherent value, are yet attractive from the veneration they are held in by every nation. The avocations of the surgeon compel him to deal more with realities than fictions—bring him into closer contact with his race—admit him behind the scenes when, in the great drama of human life, he beholds the actors unmasked and stripped, having nothing more than the common attributes of our race. He is compelled to go where the world is oftentimes not permitted to follow—to behold men sick, and mangled, and oppressed, and in these circumstances ready to lay at the feet of medical science all that is valued by the world, if they can only procure the inestimable blessing—health. It may be, perhaps, that an intelligent consideration of these things has led the medical officers of the army to be silent under their wrongs yet this does not remove their right to worldly distinctions, or the obligations of a Government to bestow these upon them.

As we have particularly called attention to this subject, it is not our intention now to extend our remarks, but we propose to bring under notice the treatment of Assistant-Surgeons in the Navy. The Government, in choosing medical officers, seek for those who have obtained the highest academical honours, and whose moral and physical endowments eminently fit them for the important functions which they are called to perform. They are entitled, therefore, to that consideration which is due to gentlemen and scholars. Yet, when they first enter the navy, they do not receive it. The Government considers it necessary that they should undergo a little further schooling, not in medical knowledge, but in the important science of humility—in order, we suppose, that, as they will have some of the honours bestowed upon them which are given to the other officers in the service, they may be so disciplined as never openly to aspire to them. Their character as men appears to be forgotten, and they are compelled to associate with boys just emancipated from school, who are engaged in acquiring the first rudiments of a nautical education—that of boxing the compass and of reefing a topsail. We are totally at a loss to conjecture why the gun-room is selected as the best place for the surgeon, when he first enters the navy, unless it is at once to humble him. This, however, is the only way for him to gain the superior privileges of the ward-room; and in his progress thither it is no wonder if, like Bunyan's pilgrim, before he gains the wicket-gate, he tumbles into the slough of despond, from which he finds it no easy matter to extricate himself. Without a cabin, without congenial society, without the means of increasing that stock of knowledge which he already possesses (for he has neither the opportunity of keeping a library, a chest being all that he is allowed to contain his books and wearing apparel, or of retirement, to contemplate those scientific truths, the acquisition of which is essential to the welfare of those confided to his care), he is a being alone in the midst of numbers, and a sufferer from the unjust regulations of an honourable service. The present race of assistant-surgeons are only experiencing, however, what their predecessors have done before them; but, instead of this being an excuse for inflicting upon them unmerited and unnecessary hardship, it is a cogent reason why they should at once be translated from the gun-room to the ward-room. Time can never make that right which is essentially wrong; and precedent goes for nothing when cited to support an unjust

act; but rather favours its immediate condemnation.

Government is right in seeing that their medical officers have had the best education; hence it requires that a candidate shall possess a diploma from one of the Colleges of Surgeons in the United Kingdom; and, in addition to this, shall be examined by the Inspector-General of Naval Hospitals and Fleets. Moreover, the regulations inform us that a favourable consideration will be given to the cases of those who have obtained the degree of M.D. at either of the Universities of Oxford, Cambridge, London, Edinburgh, Dublin, or Glasgow; or who, by possessing a knowledge of diseases of the eye, and of any branch of science connected with the profession—such as medical jurisprudence, natural history, natural philosophy, &c.—appear to be more peculiarly eligible for admission into the service; and the bait which is held out to allure a gentleman, with a university education and a doctor's degree, is—seven shillings and sixpence a day, a chest three feet six in length for his traps, and the society of boys.

We are glad to find that the attention of the profession and the public is beginning to be directed to this matter, which is certainly a disgrace to the service and dishonourable to the profession. It becomes the superior medical officers of the navy, especially, to use all their influence to bring about a change. We cannot imagine that any Government would be displeased at their remonstrance, or so stupid as to disregard it. Something is expected from them by the members of the profession, and to disappoint them would be to lower themselves greatly from that high position which they now occupy in the estimation of the entire body of medical practitioners.

It will be, moreover, greatly for the interest of the service to dispense at once with this gun-room penance of the naval assistant-surgeons. The discipline is evil in its tendency, and the men upon whom it is exercised are quite undeserving of it. Their removal to better quarters will afford more space for the strapping midshipmen to indulge in the freaks of youth when enjoying relaxation from official engagements; while it will prove an incentive to young medical men suitable for the service to enter it, which they will now be unwilling to do with a thorough knowledge of the degradation to which they must submit. The matter cannot be permitted any longer to remain at rest; and the members of the profession, in seeking to obtain an act of justice for their brethren in the service of the Government, will assert their own dignity, while they will show that they are no longer to be insulted with impunity.

ELECTION OF A PHYSICIAN TO THE BEDFORD GENERAL INFIRMARY.

It is not many years ago that the College of Physicians was so exclusive as to admit none to the privileges of the fellowship who had not enjoyed a university education. As a natural consequence, many who were celebrated for their professional abilities attained no higher rank than licentiates of the corporation. The College was forced eventually to adopt a more liberal policy, because nearly all the talent was found to be possessed by the licentiates, and it was necessary that the fellowship should be prevented from falling into contempt. The innovation was brought about by the spirit of the times, and the College has become so far liberal as to admit

general practitioners to examination for their diploma. Science recognises no distinctions, except those which mind confers; and institutions established for the honour and interests of science must, to a certain extent, feel the influence of this principle, though they may be slow to act upon it. But if a college, founded in a dark age and fostered by an exclusive spirit, has given way to the influence of the times, can we wonder that other institutions, erected ostensibly for good purposes, but oftentimes badly managed, like many of our hospitals, should be found occasionally manifesting a liberality of disposition as surprising as the opening of the College of Physicians to the licentiates of the Apothecaries' Company? Hospitals have been the hotbeds of nepotism—places where family or corporate interest has been employed for the worst purposes. To find the governors of these institutions exhibiting anything like a spirit of liberality is a wonder even in the nineteenth century. The Bedford Infirmary has set an example which other similar places may be disposed to follow, without the most energetic resistance from conservative governors. Dr. Hedley, a general practitioner of the town, has been elected a physician to the hospital, having only obtained his doctor's degree a fortnight before from the University of St. Andrew's. His election was sanctioned by the other medical officers of the hospital, and was carried without any opposition from any rival candidate. We cannot tell, of course, what motives were in operation, but we look at the circumstance as the recognition of a great principle, that sound professional knowledge and extensive experience constitute the physician. This has been recognised by universities and colleges, as their regulations now testify; and the doctrine has been instilled into the public mind not, we are sorry to say, in too many instances, with a view to benefit the people, but to promote the interests of a class. We are advocates for a university education for every member of the medical profession; but while we believe this is always desirable, it is not always possible; hence the general practitioner who has not been brought up under the fostering care of a chartered *alma mater*, but whose professional attainments are of a high order, should ever find a ready and cordial admission into the rank and privileges of a doctor of medicine. He is in every respect a *bona fide* physician, and one well calculated to discharge in the most efficient manner the responsible duties of a hospital functionary.

It seems, from the report of the proceedings at the election of Dr. Hedley, that he is not disposed to lay aside in cases of necessity the use of the lancet or the knife; and this circumstance appeared to operate unfavourably upon the minds of some of the governors. It is a false notion of honour, however, which confines the office of physician to the treatment of internal diseases, and simply prescribing for them; and there are circumstances in which he may be imperatively called to undertake manual operations, the prompt performance of which may, instead of lowering his dignity, materially increase it. Life and limb are blessings of too great a value to be endangered by a rigid adherence to professional etiquette, and we shall be glad to see every false notion of honour permanently excommunicated from the minds of medical practitioners.

The new physician of the Bedford Infirmary is doubtless a man of education, of talent, and of experience; and it is to be regretted that he

was compelled just before the election to post down to St. Andrew's to obtain a doctor's diploma. The circumstance is calculated to offend the respectable body of practitioners into whose order he has entered, and to make them look with a more unfavourable eye upon those universities which grant degrees without insisting upon residence.

[To the Editor of the Medical Times.]

SIR,—I am happy to have to append a pleasing response, alike creditable to the heart and to the head of the writer, to my simple announcement of the death of Mr. Walker, in the *Medical Times* of the 19th ult.

"To A. W. CLOSE, Esq.

"DEAR SIR,—Your letter in the *Medical Times* of the 19th inst., announcing the death of Mr. Walker, of Manchester, attracted my attention a few days since. The simplicity of truth is often the most powerful appeal to the heart, and I trust that your 'unvarnished tale' may obtain a respectable subscription for the widow and family of the amiable and talented man whose career on earth has been so suddenly (let us hope not untimely) arrested.

I knew nothing of Mr. Walker but as the author of "The Oculist's Vade Mecum;" and I regret to find such a man dying in such poor circumstances.

"I am, Sir, your very obedient,

"Ipswich, June 28. "GEORGE BULLEN.

"P.S.—Be so good as to acknowledge the receipt of the post-office order for £2."

The writer of the above concludes his excellent letter with a classical quotation which is illegible, but which I take very aptly to express the position of our late friend:—"He possessed not much of this world's good, but he was blessed with a high and noble character." He also alludes to that which gives the family of Mr. Walker a special claim upon the sympathies and benevolence of his professional brethren. Much of his earlier resources were expended in the very slowly remunerating work of an author. Whilst his "Oculist's Vade Mecum" has tended in no small degree to raise the character of provincial ophthalmic surgery, the actual outlay of its production, I believe, was only just realized during the last year of his life.

Subscriptions on behalf of his family will be gladly received if sent to any of the following persons:—

Elkanah Amitage, Mayor of Manchester,
John Windsor, Esq., Piccadilly, Manchester,
Daniel Noble, Esq., Piccadilly, Manchester;
or to

Your most obedient servant,
ANTHONY WILLIAM CLOSE.

20, Grosvenor-street, Manchester, July 1.

PROFESSIONAL EDUCATION AND RESPECTABILITY.

[To the Editor of the Medical Times.]

SIR,—The only true way to make the medical profession really respectable, is for all those in power to keep ignorant, uneducated, and ungentlemanly persons out of its pale.

Every court of examiners should be more particular in their investigations, whether for degrees or diplomas. They should "take nothing for granted;" there should be no favour; and rigid, and strict, and searching inquiry should be instituted before any student or candidate should be admitted to the honours, or receive the authority he may aspire to.

It matters very little where a man may acquire his knowledge, provided he really has it: for it is as possible for him to be competent to give satisfactory proofs of his ability and acquirements without having been at the more celebrated schools of medicine, as for others to have apparently gone through all the required ordeal and process of study, and still be wholly unfit to practice.

The general practitioner should be subject to severe censure and animadversion, at least, if he gives up an indenture to his apprentice, unless he has actually served with him the stipulated time expressed. The lecturer or professor should give no certificates unless he is quite convinced that the student had duly attended his courses. If the class were so numerous that the professor could not recollect all the pupils, he should require from them their solemn declaration and word of honour that they had only been absent occasionally, and rarely, and then only from absolute necessity or indisposition.

The shameful degrees conferred by certain universities, only for the sake of the money paid for them, are a disgrace, instead of an honour, to those who give, as well as those who take them, merely from documents and certificates, which, at least with regard to time and duration of study, often are absolutely false.

I fear, too, from recent instances, and the amazing number of young men poured forth upon the world as surgeons and medical practitioners, that our own authorities in this metropolis are not by any means so particular as they ought to be in their examination, before they give their *stat* to the tyro, and license him to inflict suffering and death upon his fellow-creatures with impunity.

It is very easy, Sir, to ascertain if a candidate be well grounded in principles, or merely ground by a grinder; and mere tickets of attendance or certificates should have no influence whatever, if the student upon absolutely necessary points be found ignorant.

I have the honour to be respectfully, Sir, your obedient servant,
SENEX.

THE DRUGGISTS AND GENERAL PRACTITIONERS.

[To the Editor of the Medical Times.]

SIR,—Your number of the 19th of June contains a letter from Mr. Ebsworth which merits some notice on your part. The encroachments of druggists upon the privileges of the licentiates of the Hall has been, and is, an evil important not only to them, but to the general practitioner; and, as you profess to use your abilities for the benefit of the medical profession, I expected something more from you than the publishing of Mr. Ebsworth's letter.

I think that that letter ought to be republished every month, as long as the injustice remains, and injury inflicted upon any member of the Hall; and I should hope that even the number of subscribers to the *Pharmaceutical Times* would not be diminished by your energetic advocacy of the privileges of the licentiates. Would you obtain the rules of the Apothecaries' Hall, and publish them; also the laws granting those privileges, with the pains and penalties annexed, also any cases and decisions.

Yours respectfully, an old subscriber,
J. POOL.

YORKSHIRE MEDICAL LITERATURE.

I being Called upon to answer the greivances of the said Ch. Mills bellow to is fut and harm and hand that honeyey being a Inflatiton very deep sitted on the nirv or bon part witch is the caus of the greivances of is Complaint more like a gangreen than a blast as for the greivences that Peeple lais to is Charge I am quite Ignorant of for I never Examinated im nor never saw Is Privarts In all my lifetime so I have made none as far as I am hable so fairwll this is the truth and no more Edmund Travis.

"The original of the above splendid specimen of the learning of a Yorkshire practitioner," says our correspondent, by whom it was forwarded, "was handed over to me by an Independent minister, who knows the writer. He is a practitioner of ancient fame; in practice before 1816."
—Ed. *Medical Times*.

ELECTION OF A PHYSICIAN TO THE BEDFORD GENERAL INFIRMARY.

A meeting of the governors of this institution was held on Monday week, for the election of a physician in the room of the late Dr. Mesham.

The chair was taken at twelve o'clock by W. H. Whitbread, Esq., the perpetual president. The attendance of governors was not so large as usual at the election of officers, probably from the circumstance of there being but one candidate.

The President having announced the object of the meeting,

Mr. C. L. Higgins, of Survey Abbey, rose and nominated Dr. George Dixon Hedley, of Bedford, for the office of physician to the infirmary, rendered vacant by the death of Dr. Mesham. He then proceeded to give a description of the progress of the candidate in his profession, stated, that after he had passed through a course of studies, he went to Paris, and had constant intercourse with the most eminent men in the profession. On his return to England, he commenced his medical career at Birmingham, and there received the appointment of lecturer on medical jurisprudence. He did not long remain there, for a highly-respectable practitioner in Bedford, Mr. Woolridge, offered Mr. Hedley a portion of his practice. This offer was accepted, and Mr. Hedley had continued his medical career in Bedford with very great success. Last week he took the degree of Doctor of Medicine at St. Andrew's. There were twenty-eight candidates for the degree, and it was announced that of that number two had acquitted themselves in the most distinguished manner: one of those gentlemen, of whom such honourable mention was made, was the candidate he (Mr. Higgins) now ventured to propose. These things spoke well for the ability of Dr. Hedley, and his character was well known by all the governors present; and in making choice of him as one of the physicians to the Bedford Infirmary, he was quite sure that the governors would make an appointment most conducive to the interests of the institution.

Mr. T. A. Green seconded the nomination.

Mr. President said, as there was no other candidate, it became his duty to put the proposition to the governors; but, before he did so, he considered it also his duty to put the case clearly before them as regarded the qualifications of Dr. Hedley. He had not one word to say against Dr. Hedley himself, for he believed him to be a gentleman of great talent and high character; but he wished the governors to bear in mind that it had hitherto been the practice at this institution to appoint a *bona fide* physician. There should be two classes of professional gentlemen there—two physicians and two surgeons; he, therefore, submitted to the meeting whether it would not be desirable to ascertain from Dr. Hedley what were his intentions as to his practice for the future. He was not aiming anything at Dr. Hedley personally, but he deemed it his duty, as president, to put the question.

Mr. C. L. Higgins said he would ask Dr. Hedley that question, if the governors thought fit. He believed that it was the intention of Dr. Hedley to give up dispensing medicines, but he could not answer for anything farther until he had spoken to him. The governors all knew that he had practised surgery with great success; and there must be a mixture of practice. He thought, if Dr. Hedley was willing to act as physician to the infirmary, it would be all that the governors required.

(Mr. Higgins then left the room to speak to Dr. Hedley.)

Mr. W. B. Higgins, of Picts-hill, inquired what was the rule in that respect?

[The President said the rule required that the candidate should have taken the degree of Doctor of Medicine: that was the letter of the rule; but the spirit of it, and the practice of this institution, had been that the candidate should also be a *bona fide* physician in practice; and he believed Dr. Witt would bear him out

in saying that was the case when he received the appointment.

Mr. Barnard said it was the feeling of the surgeons to the infirmary that it should be so. If those gentlemen now took an interest in the election of Dr. Hedley, and were satisfied with his qualifications, he (Mr. Barnard) thought it was of little matter to the governors.

Mr. Palgrave agreed with the president in the view he took of the matter, and thought there was great point in his remarks.

The Rev. C. C. Beatty Pownall said he concurred that in this institution the duties of physician and surgeon were kept entirely

separate. Mr. Hurst said, such had hitherto been the case, and he ventured to add, they would be so in the future, as long as he was one of the officers. Of Dr. Hedley, personally, he had the highest opinion.

Mr. L. Higgins returned to the board-room and stated that he had communicated with Dr. Hedley, who said he would give up dispensing, but as regarded the other part of his practice he wished to be left free. He wished to be left free to practise surgery when called in to cases.

Mr. Hurst said, he understood that Dr. Hedley would not seek for practice in surgery.

Mr. C. L. Higgins said, such was the case; he would not seek for it, but would aim chiefly at physician's practice. Of course, in a case of emergency, he would give his services as a surgeon in his own practice.

The President thought that explanation affected the case materially.

Mr. Lindsall thought, if the candidate undertook to give up dispensing, that would meet the case. He understood that he held out for practice as a physician.

The President then put the question, whether the governors considered Dr. Hedley eligible to be a candidate.

The question having been carried in the affirmative.

Dr. Hedley should be appointed.

Mr. Lindsall then proceeded to put the question. Dr. Hedley should be appointed. Mr. Lindsall wished to make a remark. The question was put. He hoped the governors understood the case exactly. Dr. Hedley would practise as a physician, but would hold himself free to attend to surgical cases.

Mr. T. A. Green understood that it was not Dr. Hedley's intention to seek for surgical practice, but that he did not wish to be shackled.

Mr. Hurst said that the governors required a man to do justice to the patients, and they could not get a pure physician in all cases. In a short time it would be found that they would have to merge the two branches of the profession.

Mr. S. D. Whitbread said, the chief matter for their consideration was, whether the surgeons approved of this appointment; and it appeared they did approve of it.

Mr. Wessle considered that there could be no objection to the candidate, as the dispensing portion of the practice had been given up.

Mr. Barker began to make one remark on a point which had been overlooked. If Dr. Hedley did away with dispensing, he did all that the College of Physicians required, to enable them to grant a license to practise as a physician. He appealed to Dr. Wist whether such was not the case.

Dr. Wist had determined to take no part in this election, but he had no objection to reply to a question. It was quite true what Mr. Barker had stated. In his own case, when he applied to the College, he was required to sign a certificate that he would not dispense medicines.

Mr. W. B. Higgins was sorry to differ with gentlemen upon any question, but he really thought Dr. Hedley was not strictly within the intention of the rule of this institution, yet he had just held up his hand for him in consequence of his high character and reputation. He could do no less than wish to see him elected, yet, as an honest man, he (Mr. Higgins) felt bound to state his opinion, that the framers of the rule did

not contemplate its including precisely such a case as this.

The proposition was then put, and carried unanimously. Dr. Hedley was called in, and

The President said he had the pleasure and satisfaction to announce that he had been elected physician to the Bedford General Infirmary; and in making this appointment he was confident the governors had secured very valuable services. As president he had felt it his duty to call attention to one point, and, as a satisfactory answer had been given, he felt great pleasure in seeing him elected, well knowing his high character and reputation.

Dr. Hedley returned thanks for the appointment. He felt greatly obliged to the governors for electing him to the office; and he did not know that he could say anything further, except that it would be his endeavour to discharge the duties of the office in such a manner that the governors should not regret having appointed him.

The thanks of the meeting were then given to the president, and the meeting broke up.

QUEEN'S COLLEGE, BIRMINGHAM.

A meeting of the Council of Queen's College was held on Saturday last, the Rev. and Worshipful Chancellor James T. Law, Vice-Principal, in the chair. The new Charter of Incorporation was submitted to the members by William Sands Cox, Esq., the Dean of the Faculty, and warmly received. Her Majesty has been graciously pleased to confer on the college most extensive privileges. Full powers have been given to "the Principal and Council" to embrace, in their system of education, laws, literature, science, and the arts.

Also to be able and capable in law to take, purchase, and hold for the use of the Queen's College and the Queen's College Hospital, any goods, chattels, or personal property whatsoever; and also to be able and capable in law, notwithstanding the statutes of mortmain, to take, purchase, and hold to them and their successors not only all such lands, buildings, hereditaments, and possessions, as may be from time to time exclusively used for the sites and immediate purposes of the college and hospital respectively, but also, for the use and maintenance of the college, any other lands, tenements, hereditaments, and possessions whatsoever, not exceeding the annual value of £2500; and also, for the use and maintenance of the hospital, any other lands, tenements, hereditaments, and possessions whatsoever, not exceeding the annual value of £2500.

Also, to have power to accept, on behalf of the college or hospital, gifts and endowments for promoting particular objects of education, or otherwise in aid of the general purposes of the college or hospital, on such terms and conditions as may be agreed upon for the purpose between the said college and the person bestowing such gifts and endowments.

With respect to the mode of electing the professors it provides:—"That whenever a vacancy shall occur in any professorship, the names of the candidates shall, in the first instance, be referred by the council to the professors, who shall make a special report to the council of the names of such candidates as, in their judgment, shall be qualified and eligible, professionally and otherwise, to fill the vacant professorship; and that the council shall then recommend to the governors, from the candidates included in such report, one whom they think best qualified to fill the vacant professorship."

It also provides:—"That whenever, in the opinion of the council, any professor ought to be removed, by reason of neglect of duty, incapacity from permanent illness, infirmity, or other sufficient cause, a report to that effect shall be laid by the council before a special general meeting of the governors, to be called for that purpose; two-thirds of whom shall have power to remove such professors; the votes of such meeting to be taken by ballot."

It also enables the council to confer on its distinguished students an honorary distinction. The council shall have power from time to time to elect such members of the college holding a diploma in medicine or surgery, or being graduates in medicine, law, or arts, or such members of the "late Birmingham Royal School of Medicine and Surgery," as the council may by their by-laws determine to be "Fellows of Queen's College at Birmingham," with powers to vote at all special and general meetings of the governors, and with such other powers and privileges as may be determined upon from time to time by the council.

It also provides:—"That all fees from students for attendance on the medical and surgical practice of the Queen's Hospital shall be paid to the treasurer of the college, for the use and purposes of the hospital; provided, nevertheless, that it shall be lawful for the council of the college, from time to time, to pay over such proportion of the fees as they shall think fit to such medical and surgical officers as are engaged in the actual duties of professors of the college and of medical and surgical officers of the hospital."

A sub-committee, consisting of the Rev. Chancellor Law, Dr. Eccles, Dr. Best Davies, and William Sands Cox, Esq., was appointed to draw up a dutiful and loyal address, praying her Majesty to be pleased to accept the most respectful and grateful acknowledgments of the college for her Majesty's great kindness in granting to the college such important privileges, to be presented at an adjourned meeting to be held on the 28th instant.

TO THE HONOURABLE THE COMMONS OF GREAT BRITAIN AND IRELAND IN PARLIAMENT ASSEMBLED:

THE HUMBLE MEMORIAL OF THE UNDERSIGNED COLLEGIATE SURGEONS AND PHYSICIANS, RESIDENT IN THE ISLE OF MAN, Showeth—

That your memorialists perceive with deep anxiety that a "New Medical Bill" has been recently introduced into your Honourable House which, instead of embodying those great staple measures that must ever constitute the groundwork of a truly liberal and comprehensive enactment for the medical practitioners of these realms, is, on the contrary, at direct variance with their highest interests, by insidiously cloaking, under the semblance of equitable registration, details most banefully pernicious to the profession and obnoxious to the public.

That your memorialists very respectfully beg leave to urge upon the grave consideration of your Honourable House that no statutory measure can possibly meet the exigencies of the medical practitioners of these realms that does not comprise the following provisions of reform, viz:—

1.—The thorough legal recognition of perfect equality of estate between the three great divisions of the profession,—surgery, physics, and general practice, by amplifying and equalizing their respective curricula of education, both classical and medical, and by conferring upon each division identity of privilege, immunity, and collegiate rank.

2.—The incorporation of the great body of general practitioners by the erection of a National Institute.

3.—The extension of a vote to all practitioners in the government of their respective colleges.

4.—The establishment of a strict registration of all practitioners.

5.—The establishment of a Central Board of Health, by which the profession may at all times maintain a position to communicate with executive.

6.—The considerable diminution of the number of existing licensing medical bodies, esp. if only there are no less than seventeen.

7.—The total suppression of empirically begun summary penal measures.

That your memorialists do, they, and her strength to, emphatically express to adding lowering

House their unqualified repudiation of the aforesaid measure, as directly tending to the retardation of medical science, and consequently as at once subversive of the best interests of their profession and immediately hostile to the public welfare.

That your memorialists do, therefore, implore your Honourable House that the aforesaid "New Medical Bill" may not pass into a law.

And your memorialists will ever pray, &c.

Robert Edward Craine. George S. C. Butler.

Thomas M. Teare. William A. Hubert.

Thomas Christian. Thomas Nelson.

John Teare. W. H. Montford.

John Quillin. A. Quathough.

Philip Elliot. J. Stubbs.

June 23.

GOSSIP OF THE WEEK.

ROYAL COLLEGE OF SURGEONS.—The annual election of three Fellows into the Council took place on Thursday week, when Mr. Edward Cutler, Surgeon to the St. George's and Lock Hospitals; Mr. Charles Aston Key, Senior Surgeon to Guy's Hospital; and Mr. Cesar Henry Hawkins, Surgeon to St. George's Hospital, were duly re-elected. After the election the Fellows adjourned to their annual dinner at the Freemasons' Tavern.

ARMY MEDICAL SERVICE OF THE UNITED STATES.—It is prescribed by law that no person shall receive the appointment of assistant-surgeon in the army of the United States unless he shall have been examined and approved by an army medical board, consisting of not less than three surgeons or assistant-surgeons, who are designated for that purpose by the Secretary of War. The medical board of examiners rigidly scrutinizes the pretensions of each candidate, taking into consideration his physical qualifications and moral habits, as well as his professional acquirements; and repews favourably upon no case admitting of a reasonable doubt.

THE INHALATION OF ETHER.—By a decree of the Government of the grand duchy of Hesse Darmstadt, *officers de santé*, dentists, and midwives are forbidden to use the vapour of ether in their operations.

FRENCH MIDWIVES.—The annual distribution of prizes to the female pupils of the Ecole d'Accouchement, Paris, recently took place in the amphitheatre of that establishment. M. le Comte Hector Lepeletier d'Aulnay presided, in consequence of the absence of his colleague, M. Edmond Halphen, from illness.

PROCURING OF ABORTION.—A trial has recently taken place in the state of Massachusetts, in which a woman of the name of Luceta Parker was charged with having thrust into the womb of a married woman, then pregnant with child, a sharp metallic instrument with the intent to cause marriage, and that in consequence the child was born dead. On the trial it appeared in evidence that the acts alleged were done with consent of the woman. The jury found a verdict of guilty, and her counsel moved an arrest of judgment, because it was not set forth that the woman was quick with child at the time the operation was performed. The judge instructed the jury that it was not necessary to prove this fact, but he deemed the question involved so important that he reported it to the Supreme Court. After argument, the Chief Justice, in delivering the opinion of the court, stated that, at common law, the court were of opinion that no indictment would lie for attempts to procure abortion with the consent of the mother until she is quick with child. It is mentioned in a note to this case, that the Legislature of Massachusetts subsequently made provision for the punishment of the offence with which the defendant was charged in a satisfactory case.

It is mentioned in a note to this case, that the Legislature of Massachusetts subsequently made provision for the punishment of the offence with which the defendant was charged in a satisfactory case.

AWFUL CONSEQUENCES OF IMPROPER SURGERY.—In the neighbourhood of Castle Island and Ballylongford, from the imperfect covering thrown on the dead victims of famine, troops of dogs prey from day to day on the bodies. This is not all: violent madness is the result, which has led these rabid animals not only to attack one another, but the cattle in the fields. The authorities and the gentlemen of the county should at once look to this.

OBITUARY.—On Sunday the 4th inst., at his house in Camden-town, deeply lamented, Joseph Curtis, surgeon, aged 47.

MORTALITY TABLE.

For the Week ending Saturday, July 3, 1847.

Causes of Death.	Total.	Average of 5 Summers.
ALL CAUSES.....	933	940

(ADVERTISEMENT.)

[To the Editor of the Medical Times.]

SIR,—I here embody the substance of my communications to your journal, which you so unfairly refused to insert, except in the form of an advertisement. You stated as your reason, that it was merely a matter of local interest, though it concerns the interests of the whole profession; and you, as its organ, ought to have denounced the proceeding of the parties in not stating the source of the diploma of 1840 as suspicious and unprofessional.

Your own unguarded and unwarranted remarks, with the scurrilous and paltry insinuations of the Editors of the Directory, render it incumbent upon me to lay a concise statement of the facts before your readers; and I feel assured they will give us credit for purity of motives and a desire to elicit truth, and expose any attempt at imposition and evasion. The facts of the case, as between ourselves, the "Medical Directory," and Mr. Ryott, stand thus:—I and my friends wrote to Mr. Churchill, to inquire upon what authority he inserted Mr. Ryott in the Directory as a graduate of Edinburgh, in 1840. Mr. Churchill, in his printed circular to the profession, requested as a particular favour that he might be informed of any one whose qualifications were suspicious, as he should exclude all such from his work. It suited the purpose of his editors to take no notice of our private letters; therefore, to get at the truth, we jointly complained of his conduct through the medium of your journal (*vide Medical Times*, June 12). This no sooner appeared in your columns, than we received an explanation from the editors of the Directory, accompanied with the return furnished them by Mr. Ryott, the handwriting

of which they requested us to identify. We did so; and in our answer informed them it was Mr. Ryott's handwriting, and that we agreed with them that the entry in the Directory and the return corresponded. These eminent editors subsequently thought it to be recant, and, with an utter disregard of truth, asserted they received from us no reply. Unfortunately for their cause, I have in my possession the original return furnished them by Mr. Ryott; an exact copy of which I enclosed for your inspection, and in confidence you will say Mr. Churchill was deceived by it. Besides, on the authority of his return, he is entered as practising as a physician. This, Sir, is not correct. He is the junior partner in a general practice. Physician, forsooth! From all the circumstances of the case, I doubt his claim to be admitted as doctor, and consequently decline to do so on the present occasion, and shall refuse to designate him as such until either the diploma of 1840, or the place from which it comes, is revealed. Being a fellow of the College of Physicians of Edinburgh, I cannot confer that title; and as Dr. Craigie, its secretary, is unable or ashamed to inform me where the diploma is, I have strong suspicions of its genuineness. We have known instances of colleges having been imposed upon as well as individuals. Mr. Ryott's partner cannot produce it, or name the place at which it was purchased; otherwise, he would have done so when he attempted, and failed, to get his diploma as a qualified practitioner to the Thirsk Book Club, its rules prohibiting all unqualified persons. The editors of the Directory, little scrupulous what means they use in defence of their protégé, Mr. Ryott, are unable to tell whence it is derived. They say the degree was obtained after residence and examination. This I shall show is gratuitous falsehood. In the date 1840, both in the original return and the Directory. The common acceptance of the words "residence and examination," being a term of years of residence and examination, proving the competency of the candidates to practise; which Mr. Ryott never underwent. He was not absent from Thirsk for more than a few days, during that year. In 1838 or 1839, he, being recently out of his apprenticeship, engaged on his duties as dispensing and visiting assistant to his present partner. In the year 1842 he was away from Thirsk for a few weeks, and then it was I presume, that the residence occurred and the diploma purchased; all which proves that his spurious degree either came to order by post, or was obtained. As to the intrinsic value of this vaunted diploma, what does it amount to? Does it give him any title to practise as a general practitioner? I answer—No. Why, then, is it so tenaciously held to, while its putative parent of 1840 is so indignantly kept back? Simply, because it would disgrace and degrade its offspring. These young men, the editors of the Directory, have learned, it seems, from another source, that Mr. Ryott is a duly and legally qualified. The source from which this information comes is obvious enough, and I beg to give it a flat contradiction; at the same time informing them that he has not the shadow of a legal qualification. From the same source they are informed, he is in considerable practice, "too successful to be agreeable to his competitors and detractors." Such are the uncourteous and unjust remarks with which you have allowed the columns of your journal to be sullied. These editors were probably not aware, at the time they penned the foregoing language, that their protégé, Mr. Ryott, author of the "polite and temperate communication" to this journal, by a gross violation of the act of Parliament, attended as substitute for his partner, the Postmaster-General, the remuneration for which is rather below the average in this country. Moreover, he is a member of the Union Friendly Society (a respectable club), again, as substitute for his partner, not being qualified according to their rules, for which he receives the sum of 2s. per head per annum (the lowest pay of any of the friendly societies in this neighbourhood), and which any "highly-esteemed" practitioner would consider derogatory to the dignity of the profession. Well may he have a "considerable practice." *Sum teneatis amici.*

In conclusion, I would recommend to these young gentlemen of the Directory to be more cautious in admitting to the body of their work any party who does not comply with the instructions of their printed circular—treating all such as unworthy of confidence, even when such return is accompanied by an order for their work. Without this they need not calculate upon the support and countenance of the right-minded of the profession.

I am, Sir, your obedient servant,
J. Thos. Harrison, M.D., F.R.C.S., &c.

COURSE OF LECTURES ON CLINICAL MEDICINE,

Delivered in the THEATRE of QUEEN'S COLLEGE, Birmingham.

By SAMUEL WRIGHT, M.D.,

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and formerly Senior President, of the Royal Medical, Royal Physical, Hunterian Medical, and Cuvierian Natural History Societies of Edinburgh, &c.

Amenorrhœa, two varieties of; circumstances affecting the advent of the menstrual period, effects of its absence before the age of twenty and after; examination of patient, particularities to be observed; symptoms usually attendant upon *amenorrhœa emansionsis*, treatment of this in its simple forms with sympathetic fever—with debility; *amenorrhœa emansionsis* arising from a scrofulous constitution, *amenorrhœa suppressionsis*, causes of it, precautions to be observed in treating it; routhism not available; treatment by iron and aloes; exceptions to the use of these, cases in the hospital; treatment of *amenorrhœa* arising from dyspepsia; from plethora; from rheumatism, from debility; from cold, treatment of symptoms under particular circumstances, chlorosis.

GENTLEMAN.—I have a few observations to offer upon the subject of *amenorrhœa*, several cases of which you have lately seen treated in the hospital. Nosologically speaking, *amenorrhœa* is of two kinds, which are respectively denominated, *amenorrhœa emansionsis*, and *amenorrhœa suppressionsis*. Practically speaking, they differ little, either in the symptoms which they present, or the treatment which they require. In the former case, the menses have not as yet appeared; in the latter, their periodical occurrence has been arrested.

The advent of the menstrual period is very much regulated by climate, temperament, and mode of life. In hot countries, this period happens to early youth; in cold countries, to later; in mild climates like our own, the age is midway between those opposites—from fourteen to fifteen is the age, as a rule, with us. To this rule, however, there are various exceptions. Females of a sanguine, excitable, plethoric temperament, and those who are engaged in outdoor active occupations, and are well nourished, sometimes menstruate as early as at twelve years, and even sooner than this. For opposite reasons, also, the commencement of this important discharge is often delayed beyond the average time. You occasionally meet with instances in which the catamenia have not once made their appearance through even a protracted lifetime; and this, without the general health having suffered, except at the particular period when the function ought to have been established. From the fourteenth to the eighteenth year, and perhaps later than this, sympathetic disorder is chiefly seen to be consequent upon the non-occurrence of the menses. If the patient get beyond the twentieth year without having menstruated, the

constitutional and local symptoms generally subside, provided there be no structural or other definite organic causes to account for the anomaly. If, in *amenorrhœa emansionsis* continuing past the age of twenty, there be much suffering, general or local, you may be suspicious of some physical condition of the uterus being the source of the trouble. Malposition of the organ, or imperforation of the hymen, may be its cause.

It is chiefly in the early stages of the *amenorrhœa* I speak of, that those of you who may hereafter practise physic exclusively, will be consulted. In the more advanced forms, the cases will generally require to come under the care of the surgeon, because of the mechanical assistance then needed.

When a patient so situated comes before you, the leading object to be had in view is, of course, to find out the cause of the suffering. In searching for this, always let your questioning and manner comport with the true dignity and delicacy of gentlemen; there are certain queries to be put—consider their seriousness, and the proper gravity becoming you, when putting them. And let no condition in life prompt an exception to this most necessary rule. Mothers, or adult female friends, generally companion invalids of this class; direct your more particular inquiries to them, as you have observed me do at the hospital. You will mostly find them fully prepared for all your leading interrogatories.

In the majority of cases of this class that you meet with, there is nothing more the matter than simply those local pains, with their various sympathies, which precede by a few weeks, or a few months, the advent of menstruation. A dull, heavy, dragging pain in the loins, and something similar in the lower part of the bowels; shooting pains down the thighs, cramps of the legs, and coldness of the feet; headache, loss of appetite, and flatulence; waywardness and irritability of temper; feverishness, and many other such like things, are the protean concomitants of *amenorrhœa emansionsis*.

In these instances it is better to do nothing more than relieve the more urgent symptoms, and leave Nature to do (as she is promising) the remainder unassisted. If the bowels be costive, give three grains of blue pill, and the same of camphor or hyoscyamus, at bedtime, and a black draught, or a dose of rhubarb and magnesia, the next morning. Every alternate or even third night, let the feet and legs be immersed in hot salt water. Give twice or thrice

daily from five to ten grains each of carbonate of soda and nitrate of potash, if there be much fever; and, if the stomach need it and will bear it, make the vehicle of those substances a bitter infusion say gentian or calumba. Prescribe regular out-door exercise, and judicious diet. These are two most important points in the treatment of the ailments I speak of. There is generally a great disinclination to walk; the patient likes the semi-recumbent posture, and perhaps falls asleep half a dozen times a day. The consequence of this is, an increasing disinclination for fresh air and exercise, and sleeplessness at night-time. The more they sit and doze, the more they desire to do so; if they wander about the house, they consider that walking enough; and they will eat all kinds of indigestible things, and imagine they are doing the stomach a service. Be particular in your directions and inquiries concerning these matters. Let your patient's exercise be regularly taken in the open air, where there is some salubrious oxygen to breathe; let her eat only at stated times, and of what is nutritive and easily digestible.

Other cases you meet with, in which, along with the pains I have mentioned, there is great nervous debility, with constant chilliness of the surface, instead of sympathetic fever. Here, your object should be to rouse by diffusive stimulants, and sustain by tonics and good food. You saw an example, some months' back, in the person of an out-patient named Hayes. She was sixteen years of age, had never menstruated, and, along with some local suffering, laboured under considerable general debility. She had an exsanguined look; tongue pale and trembling; scarcely any appetite; pulse 98, small and feeble; bowels costive and very flatulent.

Milk agreed with her, and she was ordered: take it for breakfast and tea; beef or mutton, with old bread, for dinner, additionally to any light pudding, and a glass of port wine half an hour afterwards; sago or arrowroot for supper. The following were her medicines:—

R. Infusi cuspariæ, ʒviij.; ammon. carb., ʒij. sp. eth. nit., ʒij. Misco fiat mist. cujus cap coch. ampla duo ter die.

R. Pil. coloc. comp., ʒij.; assafœtidæ, ʒi. Misco et divide in pil. xij. quarum cap. ij. omni nocte.

Under this treatment the girl quickly began to improve; her spirits rallied, and her strength and appetite increased daily. Coincident with this change was a corresponding lessening of

various pains that had troubled her: the circulation became regular and well balanced, and nervous vigour and action pretty equally distributed. At length there were no local pains or congestions, and shortly afterwards (within a month of commencing her treatment) the menses appeared, and she was quite free from complaint. She was to call upon us again if these did not return in due course; but, not seeing her, I conclude that their periodical visits were regular.

You meet with other instances, again, in which the non-appearance of the menstrual secretion is due to a scrofulous diathesis or cachexia. You saw a case at the hospital, at about the same time as the one above mentioned. We ordered her nutritive food, change of air, warm aperients, and three-grain doses, thrice daily, of hydriodate of potash, with carbonate of soda in bitter infusion. She benefited by this plan, and menstruated in about seven weeks, and continued to do so; but the discharge was scanty and high coloured. You generally find it so in such cases. In the worst of them, they rather resemble periodical leucorrhœa than genuine menstruation. These patients are apt to get into an anæmic state, and in consequence to suffer from local or general dropsy. It is when the blood is not in due quantity, or when the quality of it is impoverished, that the great services of chalybeate medicines are shown. In such cases, they are often invaluable; but, if their best effects are to be obtained, they must be administered with discrimination.

Amenorrhœa suppressionis is an ailment with which you will frequently meet in your career of practice. Often you will be able to relieve it without much trouble; but oftener, perhaps you will find it intractable in the extreme. It is especially so with strumous subjects.

Suppressed menstruation owns a variety of causes. Amongst the most common, are exposure to cold, especially exposure of the feet whilst the catamenia are present (one of the worst cases I ever saw, arose from a young lady putting her feet into cold water to arrest the discharge that she might go to a ball); acute diseases; excessive exertion, or anxiety; profuse bleeding, or mercurialization; sedentary pursuits, dissipation, impoverishment, &c.

In treating this, as in treating the other variety of amenorrhœa, make it your first object to discover the cause of the irregularity, and your second to comprehend all the symptoms which accompany it. You will thus, and only thus, get a right clue to an efficient mode of treatment. In doing so, you will find that there is no such thing as uniformity or routine to be observed, but that almost every case presents some peculiarity in which it differs from every other, and which requires that its treatment shall differ accordingly. Age, temperament, mode of life, climate, and various other things, give a singular diversity to the symptoms accompanying amenorrhœa.

If you let routine rule in such cases, you will make one half of your patients worse, and not cure the other. It was the fashion, many years ago, to believe certain preparations of iron to be specifics in amenorrhœa. That very doubtful, and certainly very dirty, commodity, known by the name of carbonate of iron (a peroxide for the most part), used to be administered in drachm doses, disguised in treacle, to excite uterine action. You may readily imagine in how far several such doses daily would operate to the cloying of any ordinary appetite. Then that nauseous nastiness, compounded of opposites, called Griffith's mixture, became a regular routine potion for amenorrhœa, no matter what the causes from which this might have sprung, or the symptoms which might attend it. What mischief was done by this blindfold sin against therapeutics, happily for the perpetrators, lives only in conjecture; but we were very near having some evidence of it the other day in the person of a very feverish patient, for whom a subordinate, in my absence, prescribed the dirty draught alluded to.

Aloes, again, either alone or conjoined with

various aromatics, was once thought a *sine qua non* to the efficient treatment of amenorrhœa. No matter what the cause, or the characteristics of the case, amenorrhœa was amenorrhœa, and aloes was aloes—and so the practice ran. How many abortions occurred in thus treating cases in particular, and how often hemorrhoids were produced in thus treating them in general, pathological history does not inform us. I have seen more than one pitiable example of the latter, in the case of plethoric females, whom depletives or febrifuges would have better served. In another case, somewhat similar, the abuse of the drastic purge caused a most distressing prolapsus uteri. Mind, I am not condemning aloes, rightly combined, as a remedy in amenorrhœa—in certain forms thereof it is most valuable; the condemnation applies to the indiscriminate and unguarded use of so potent a remedy.

Let me again tell you that there is no specific form of treatment applicable to amenorrhœa: you must study each case of it separately, and treat it accordingly, or you will never treat it aright.

Now, to mention a few of the cases you have seen treated in and at the hospital.

Mary Hackett, aged twenty-three, was admitted, under my care, on the 5th of November last year, the subject of amenorrhœa. It was of four months' duration, and had supervened upon dyspepsia. We learned that, for upwards of two months prior to the cessation of the menses, she had been dyspeptic: appetite bad; frequent eructation or vomiting; bowels costive. This state, as at first manifest, became aggravated when the uterine function ceased. At the time of her admission it was somewhat severe: tongue covered with a thick brownish fur; urine scanty, thick, and high-coloured; faces lighter coloured than natural. With ordinary diet, she was ordered the following:—

R. Infusgentiane comp., ℥viij.; sodæ bicarb., ʒij.; sp. eth. nit., ʒij. Misce fiat mist. cujus cap. coch. amplia duo ter die.

R. Pil. coloc. comp., ʒij.; pil. hydrarg. ʒj. Misce et divide in pil. xij. quarum cap. ij. omni nocte.

This treatment suited the girl perfectly well for the space of a week, at the end of which time, the hepatic secretion having become restored, it was thought advisable to discontinue the blue pill. Five grains of compound colocynth were given every night, and the mixture as before. After the lapse of three weeks, the catamenia appeared; and before five weeks had passed the girl left the hospital well.

In this case, as I have said, stomach and bowel disorder was the source of amenorrhœa: the history of it clearly told us so. Dyspepsia first made its appearance, and cessation of the menstrual function came as a consequence. What better, then, could we do than treat as in usual gastro-intestinal disorder? We did so. This disorder gradually disappeared, and its exit was marked by a return of the menses.

Contrast this case with one which happened in my practice, five years ago, at the dispensary. A girl of sanguineous temperament, aged twenty-two, came under my care for excessive swelling of the right leg. Mr. Carter, the house-surgeon, chanced to come into the room as I made my first query, which was concerning the uterine function. I found that she had not menstruated for upwards of six months. The swelling in question had existed for rather more than a fortnight. The leg was enormously swollen, and the opposite leg very slightly. For some time past she had grown fat, owing to a sedentary occupation; and upon this obesity amenorrhœa had supervened. She had had itching, and shooting pains, about the uterus and lower part of the rectum, accompanied with tenesmus, and straining on micturition. She was ordered a saline purgative immediately, to be followed by twelve leeches to the right groin. The purgative acted profusely, and the leeches bled so well that pressure had to be used to arrest the hemorrhage they caused. She needed no more

treatment. Within three days the swelling of the leg had disappeared, and within a fortnight the patient menstruated.

Here, it was evident that constitutional plethora was the remote cause of the ailment. The immediate cause was probably congestion of the uterus, and of its contiguous structures. The symptoms would warrant this belief, and so would the results of the treatment. What would have been the issue of this case had we given aloes, or some stimulating iron mixture?

The case of Frances Child I mentioned to you when treating of rheumatism, for which affection she came into the hospital. Her menses ceased when her rheumatic seizure became established. She was treated exclusively with soda, an aperient excepted. Under this treatment her rheumatism subsided, and before she left the hospital her catamenia had returned.

Elizabeth Matthews, aged twenty, came into the top ward on the 23rd of April, this year. She was the subject of amenorrhœa, apparently from a defect of the *vis vite*. She was reduced in her physical powers, but how or why we could not learn. She was not emaciated, but from her exsanguined appearance I was led to suspect an impoverished state of blood, therefore ordered her the following:—

R. Infus quassie, ℥viij.; tinct. ferri sesquichloridi, ʒij. M. ft. mist. cujus cap. coch. amplia duo ter die.

R. Pil. coloc. c., assafetide, ext. hœcy., an. ʒj. Misce et divide in pil. xij. quarum cap. ij. omni nocte.

This girl occupied the top ward, and you remember she interested us from a curious tingling and pricking sensation of which she complained in both mammae. I told you that, *ceteris paribus*, this was a suspicious feature, but not necessarily so, because it was sometimes found connected with amenorrhœa arising from general causes; so it seemed to be in this case. As the girl improved through the chalybeate treatment, this particular sensation declined, and altogether disappeared as menstruation became established, which was within three weeks of her admission. She staid in the hospital more than another fortnight, and then left in good health. This was a case that seemingly called for a chalybeate: such was prescribed, and it answered well. I preferred, as I always do, a light iron tonic; if this do not serve, I am not aware that the heavier class will be of any avail. I am fond of the sesquichloride, or the ammonio-chloride, or the citrate, or the ammonio-tartrate, or some such compound, which combines the advantages of solubility with comparative decency of taste.

Amenorrhœa often arises from cold. In many instances these cases are quickly curable; that is, the cold removed, the uterine action is restored in consequence. Diaphoretic and febrifuge treatment is often all that is necessary. I have lately had a case of this kind at the dispensary. The girl had been sitting on some wet grass playing with children. She became cold and shivering, and went home with considerable feelings of languor. Her menstrual period was approaching: she passed over it, labouring under simple fever, that was much aggravated at the time the catamenia ought to have appeared. Febrifuges, with gentle mercurials, and cautious living, improved her state, and she afterwards menstruated regularly.

Perhaps if her cold had been taken immediately, or shortly after menstruation, instead of just as it was expected, no irregularity would have been the consequence, had she been properly treated.

We had a similar case in the hospital three months ago. The girl got her feet wet, and suffered from influenza, for which she came under treatment. She had not menstruated since taking cold, five weeks previously. She was ordered salines and aperients, and her feet to be put into hot water every other night. She improved in a very short time, and was then given a chalybeate tonic, which she took for the further period of three weeks, but without any return of the catamenia. This girl was very lazy, you remember, and, thinking she was not likely to be

much better by lolling on a bed in the hospital. I ordered her dismissal. I have no doubt good exercise at home would go far towards re-establishing her health. We had three or four such cases all in at once, you know. I do not think one of them would have ever got well by good hospital living and idleness. So I dismissed them one by one, and have no doubt that domestic and other labour would go far towards completing their restoration.

Under certain circumstances, you are obliged to treat first the symptoms of amenorrhœa. This is particularly the case when there is a vicarious discharge. This may happen from an organ from which hemorrhage is of consequence, as from the lungs. It may first be merely vicarious, but the discharge may become established and end fatally. It is much more serious to have hemorrhage from the lungs than the uterus, though the quantity of blood lost be the same. Hematemesis, again, you often have, vicarious of menstruation. You had better look to this at once, or the habit may become established. I have known more than one instance of the vicarious action having become permanent, even though the function of which it was the representative had been restored. This was through neglect. It was formerly the fashion to encourage the periodical discharge of blood, no matter what the source of it. Let me tell you, it is much better to have it from the proper source than from any other; and further, that it had better be retained altogether than have such organs as the lungs and stomach for its opportunity of exit.

Always treat first the symptoms of amenorrhœa when they appear to be paramount. These subdued, proceed to treat the original ailment according to the indications which it may furnish. But have no crotchets or prejudices about it: act according to rational suggestions, the result of well-weighed and well-sought evidence.

Chlorosis is a sort of cachectic condition to which females are reduced through a continuance of amenorrhœa. It is characterized by a peculiar greenish-yellow hue of skin, pearliness of conjunctiva, and extreme debility. There is generally, in such cases, a capricious appetite, or a total loathing of food; irritability, and peculiarity of temper; irregularity of bowels, and flatulence; urine scanty, and loaded with lithates, or profuse and, as pale as water; hysterical symptoms; perhaps anasarca, from the laxity of tissue and impoverishment of blood; quick, weak, irritable pulse; palpitation of the heart frequently; and other of the various symptoms which are characteristic of debility. Some of these cases acquire an extraordinary character, and often to the inexperienced practitioner suggest fearful suspicions of most formidable ailments. Into those they are apt to degenerate if neglected, and into none more commonly than into phthisis. Continued chlorosis often begets a cachexia that ends in tuberculosis.

You have seen one case of chlorosis in the hospital under my care during the last six months. It was in the person of Mary Griffiths, aged nineteen, who was admitted Jan. 28: It had existed about two months, and she had not menstruated for six. She was ordered infusion of gentian and carbonate of ammonia, thrice daily, and colocynth pill at night, with full diet. At the end of a week, her circulation having improved, as also the tone of her stomach, sesquichloride of iron was substituted for the ammonia in her mixture. Whilst taking the latter her menses appeared, but the iron subsequently disagreeing with her, quinine was given in its stead. This suited her excellently, and on the 20th of March she left the hospital well.

It is often advisable to let ruling symptoms be your first guide in the treatment of chlorosis, but the main plan of treatment is the stimulating and sustaining. Look to the general secretions, but look also to the strength!

Dr. Aldis has been appointed one of the physicians to the Metropolitan Free Hospital.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILLIAMS, M.D. (Edin.), M.B.S.
Physician to the Royal Infirmary for Children, &c.

(Continued from p. 368.)

In my lecture to-day, gentlemen, I have to continue the subject of *Hydrocephalus*. You will remember that when I last addressed you I spoke to you of the usual symptoms indicative of the existence of the disorder I called *tuberculous meningitis*, and which I said constituted the greater number of cases of what we see in large towns as "water in the brain." This disorder, although distinctly and sufficiently well marked as it is by these symptoms in most cases, yet in others is by no means so easy of diagnosis: for brain disease may exist in children, and present an anomalous series of symptomatic phenomena. I have already told you that the disease may be so masked by the *secondary* gastro-intestinal complications, such as vomiting and constipation, that its real nature may be overlooked; sometimes the disease runs its course without any full exhibition of its peculiar symptoms—no other signs appearing save those which show themselves at the beginning of the attack, until, as life begins to fail, when various signs of constitutional distress announce the impending dissolution. In other cases no usual first stage is evident—the malady runs its course so rapidly that it appears to begin with the second. You will find some good remarks connected with this point in the works of MM. Berton and Trousseau. A child was admitted into the hospital which seemed rather disinclined to move, but continued to suck; it had no convulsions until the day before it died, when its head was thrown somewhat back. On inspection after death, tuberculous deposit was found on the pia mater, with softening of the superficial layers of the brain.

Guersent has shown the possibility of a complete suspension of all the morbid phenomena at the beginning of the second period. When I speak of *latent tuberculous meningitis*, I shall dilate more fully upon these points.

I do not think, from my own experience, that sex has much influence on the production of the malady; my proportions are nearly equal, a little in favour of the male sex as to frequency, but by no means sufficiently so as to lead me to attach importance to it.

With respect to age, I should say the disease is more frequent at from two to five years of age than at any other time, but much earlier and later, also, you will meet with it.

Some think *season of the year* has an influence on its production. Guersent considers it more frequent in "spring;" Piet, in March and July; and Rilliet, in March. I can state nothing decisive on this point.

The main cause of the disorder is the existence of the serofulous diathesis—it is a manifestation of the same. All such causes as dentition, anger, fright, &c., as are given by different authors, are far too vague to require comment. Like all other affections, the outbreak may owe its immediate origin or exciting cause to various disturbing circumstances apart from the general affection, but this latter must always be kept in view.

The prognosis of tuberculous meningitis is bad in the extreme, so bad that Rilliet asserts he has never seen a single case terminate favourably; and Ruzf and Piet confirm this opinion.

I must differ, however, with these writers, great as they are, for I believe that the affection in some few cases, when not prolonged beyond the commencement of the second period, may be brought to a happy issue. Rare, indeed, the cases are, and determinate and persevering must be the treatment, the true nature of the malady being diagnosed at once. I have had under my care three cases, which have been averted from a fatal termination after the second stage has been attained; and have had others in which being warned by vomiting, constipation, and convex fontanelles, I have acted

so strenuously that the disorder has not gone to any further extent. Of course it will be in such instances always resolvable into a question of diagnosis, and in the latter class of cases a doubt in the minds of some may exist as to how far these symptoms really indicated the meningitic affection, or were, on the other hand, evidences of cerebral congestion alone.

I have now to draw your attention to the morbid appearances observed on inspection after death. In the greater number of cases you will always find that at the base of the brain there exist evidences of inflammation in the form of an effusion of whitish, rather thick or concrete lymph, or concrete yellowish, purulent-like matter, having granulations mixed up with it. Sometimes these granulations are surrounded or imbedded in but very little indeed of these kinds of effusion, the granulations themselves being almost the only deposit. On looking at the convexities or the tops of the hemispheres you will find nearly the same appearances as at the base. Sometimes they are very evident at the base and not on the hemispheres; but I have met with but one case in which they were present at the latter, and not at all in the former spot; but I have, two or three times, seen them at the base and not on the hemispheres. These granulations are generally seen in the condition of minute whitish, or greyish-yellow little bodies, having a greater degree of hardness the greyer they are. Sometimes, from their minute size, and the very slight protuberance they form, they are not readily perceptible, unless the membrane be held against the light, when they become at once visible, or if, as advised by Rilliet, the layer be placed upon a slip of glass. The number or quantity of them varies considerably, from two or three to a number too numerous to count. Their immediate locality is beneath the arachnoid, or on the pia mater. But they have been found on or in almost every portion of the contents of the cranium. When the deposit either of effusion or granulation is considerable, it often follows the course of the greater veins. Although isolation, comparatively speaking, of the granulations, or of the semi-confluent yellow masses sometimes found, is generally observed, in other cases the granules or masses become connected together so as to form a continuous plate or patch. But you must recollect that, although extra-vascularity, infiltration, or effusion of more or less gelatiniform lymph or concrete yellow matter is frequent, yet that the essence of the disorder lies in the granular tuberculous deposit which may exist with very slight if any vascularity or effusions.

The next most frequent phenomenon observed in my experience is *effusion into the ventricles* of a limpid colourless fluid. The quantity varies sometimes, being but slight, at others, when the case has been of slow progress, very considerable: about eight ounces is the largest amount I have seen. Sometimes the effusion is turbid or flocculent, even coloured, and presenting floating particles, resembling albuminous or purulent matter, and, in all likelihood, owing to the breaking down and admixture of the ventricular parietes with the effused blood.

Next to the effusion comes softening of the central white portions of the brain. This *ramollissement* varies in intensity and extent: the cerebral tissue may be only a little less firm than natural, and involved but to a limited extent, or the corpus callosum, the fornix, septum lucidum, and other parts forming the walls of the ventricles, may be so softened and broken down as to present no trace of their natural form and structure.

Now, gentlemen, think of these three grand phenomena as the lesions constituting the common form of *hydrocephalus*: tubercular granulations at the base or hemispheres, with meningitic inflammation there; effusion of fluid into the ventricles; softening of the central portions of the brain. Remember that you will almost always find evidences of the former, which is the primary lesion in the disease; the others are secondary phenomena. Sometimes you will

and much effusion, and very little or no softening, or much softening and no effusion. They bear no definite or constant relation to each other, so far as intensity goes. There occur also a limited number of cases in which there are seen evidences of inflammation of the pia mater at the base, sometimes at the convex surfaces of the brain, too, in which the effusion is always *concrete*; but yet no distinct tuberculous matter or granulations are to be detected by the most careful observation. These cases, accompanied often by effusions into the ventricles, run the same course, present the same category of symptoms as do the others, and occur in a like scrofulous constitution. These cases are ones of scrofulous meningitis, unaccompanied by the deposit of tubercle—at least, I regard them as such. Some French pathologists call this peculiar concrete effusion *tuberculous infiltration*, and endeavour to establish its identity with *tuberculous meningitis*; but much further research and observation are necessary before this identity can be established. There occurs another class of cases, also, in which the effusion into the ventricles is very considerable, and any other lesion scarcely to be appreciated. In these examples the granular deposit exists notwithstanding, slight though it be, and constantly overlooked; but I have always been able to detect the presence of yellowish leucular discs at the base of the brain. It is in such cases as these, however, that stress should be laid upon the ventricular effusion, as the lesion giving rise to the more important symptoms or fatal event.

A less common lesion, or more unfrequent complication, you will now and then meet with, is the extension of the granular or tuberculous deposit down the medulla oblongata. Deposit of tuberculous matter in the substance of the brain or cerebellum, or upper part of the spinal cord, is also now and then seen. In four cases I have seen this complication: in one, a girl of ten years of age, there existed a tubercle, about the size of a pea, in the white matter of each hemisphere, in a state of rather softish calcareousness; in another, a boy, on tracing the crus cerebri downwards on the right side, a tuberculous heap, of the size of a marble, hard and corrugated at the circumference, was found; a third occurred in a case which Mr. Barlow and myself examined the other day. In these instances there was no softening at all of the cerebral matter adjacent to the morbid deposit; but other persons have found in such cases *red softening* present. Not only this, but true *cerebral apoplexy* has been observed in like instances. Whilst *cerebral congestion*, you must know, is one of the more common affections of infantile life, *cerebral hemorrhage* is an event of rarity: still, rare as it is, it is met with more frequently connected with tuberculous deposit than as a simple affection. You must not confound the *red softening* I spoke of just now with the effusion of blood in the softened cerebral substance around the tuberculous matter, and which constitutes the *apoplexy*.

One of the most interesting cases I have had at this infirmary, and which some of you had an opportunity of seeing, Mr. Dendy, Mr. Barlow, and myself examined last Thursday (June 10th). This patient, a boy, who had previously been in St. Thomas's Hospital, came under my care for what I considered scrofulous disease of the cervical vertebrae, with involvement of the upper part of the spinal cord; and it gratifies me to say the diagnosis was right, although the signs and symptoms were very obscure. Still it was very evident the case was a complicated one, and the disease of the bones was not all that was the matter. This boy had complete loss of power from the shoulders downwards, with great diminution of sensation; the stools passed involuntarily, and the catheter was obliged to be resorted to; now and then there was some slight delirium during sleep, and slight convulsions towards the last, with great distortion of the features just before the fatal event. The head was never moved but by the aid of his mother, and he often

complained of great pain in the head, saying it "burnt." But the intellectual faculties were very acute and perfect until the stupor supervened, about eighteen hours before death. There were other interesting symptoms I cannot speak of now; and suffice it to say, that we found after death the following lesions: I give them to you as I noted them down at the time:—

Emaciation extreme; capillary development very considerable over the extremities, &c.; eyelashes long; spinal column straight; abnormal quantity of fluid in spinal theca; spinal cord at top softened; anterior portion softer than the posterior; yellow hardaceous or scrofulous deposit existing plentifully beneath the lining membrane of the anterior portion of the upper part of spinal canal; second, third, and fourth vertebrae affected with scrofulous disease; skull much and densely ossified, but symmetrical; much congestion of meningeal vessels; brain somewhat compressed; convolutions not so rounded as usual; sulci less evident than common; granular deposit on the edges of the hemispheres, particularly on the margin of right; slight milky effusion there, with some along the course of the larger veins; ventricles largely dilated, containing from $\frac{2}{3}$ to $\frac{6}{5}$ of clear fluid; no softening of central parts; choroid plexus rather paler than natural; granular deposit at the base of the brain, abundant between the corpora pyramidalia.

With regard to this case, I would just call your attention to the great development of hair over the body, and to the tuberculous deposit; next, to the very great amount of cerebral disorder, and yet the almost complete want of the usual symptoms during life, for those which did exist were chiefly referrible to the spinal complication.

In the greater number of cases you will find that, besides on the meninges or in the brain, tuberculous deposit will be met with in some other organs or structures of the body. Often the child is in a state of incipient tubercle of most organs; sometimes, however, you will not be able satisfactorily to decide that the morbid product exists elsewhere—at least, such has happened to me in two cases. In many I have only examined the contents of the cranium, and, therefore, cannot say what elsewhere existed; but, when I have had time and opportunity to examine the bronchial glands, &c., I have usually found it. Some French writers establish the rule, that the deposit is *general*.

There is a lesion stated by Ruz, Rilliet, and Barthéz, and more lately, I see, by Dr. Budd, his "Croonian Lectures," to occur very commonly in infants dying of "hydrocephalus," viz., semi-transparent or gelatiniform softening of the stomach. I cannot speak from my own experience of the immediate connection of the one with the other.

Sometimes you will find irregular ossification of the cranium, parts not ossified you might expect would have been, or the skull very unsymmetrical in development around its *imaginary axis*.

The general aspect of the child is always that indicative of a debilitated or naturally weak constitution, mostly scrofulous, often intensely so. I have now told you of the more important and essential lesions of the "*acute hydrocephalus*," at least, such as I see it. I might have mentioned some other, and minor ones, such as enlargement of the glands of Pacchioni, an opaline condition of the arachnoid, &c. &c.; but for these I must refer you to the more minute morbid anatomists of France, especially MM. Rilliet and Barthéz.

You might ask me the question, Can definite, distinct, and constant relations be traced between the more important lesions observed after death and the symptoms which have occurred during the life of the patient? In the present state the physiology of the nervous centres, both the sick and of the sound child, I must confess we can only be sure of the more general relations, for as to predetermining a particular lesion from a particular symptom, it is out of the ques-

tion. We cannot say, that if the child has been blind, or has suffered irregular dilatation of the pupils, that here we certainly shall have the halami, or corpora quadrigemina, or geniculata, suffering pressure from fluid in the ventricles, or from much effusion at the base of the brain, because we know that these symptoms may be sympathetic, the result of an injurious influence radiating from other parts. In fact, we may have simply softening of the ventricles. We cannot be sure that, if paralysis of the upper extremities has ensued, there shall be found pressure on the halami, or if of the lower, on the corpora striata. We cannot affirm that, if there has been much disturbance of the mental functions, there shall be found deposit pressing on the grey matter of the cerebral substance; or, if the coma has been at slight, the periphery will be more affected than the base; or, if the coma has been early and profound, there will be more effusion or exudation at the base than on the margins of the hemispheres. I cannot tell you the symptoms more surely indicative of softening than of effusion, or those more evidently pointing out the want of either, but proving the existence of much concrete deposit or granulation, either at the base or on the convex surface of the brain. I cannot indicate those symptoms which would surely prove to you the existence of tuberculous matter in the substance of the brain itself.

We may venture to say, generally, that the deeper and more early has been the coma, the greater the quantity and the sooner the effusion or exudation has taken place. But it may be either in the ventricles or at the base. We may hint that such symptoms as stupor and coma are indicative of compression, yet we know that they exist in hydrocephaloid disease where there is no such thing. We may say, also, that vomiting, increased sensibility of the special senses, and delirium, are indicative of irritation, and that cerebral respiration is indicative of exudation or effusion having ensued somewhere. But how vague is all this!

Dr. Abercrombie and others have proved that all the symptoms of pressure may exist, and yet only a degree of softening of the central parts, without any effusion, be found. Andral has shown that softening and complete disorganization of the same parts may exist not only without any symptoms of pressure, but without any direct cerebral symptoms in the adult. Schweigger has stated that the ordinary symptoms may be wanting, and yet the usual morbid lesions be seen after death—the transit to which shall commence with coma. Dr. Bennet has seen flinging back of the head and opisthotonus, with a rigid state of the muscles of the upper extremities, exist in a very marked degree, and yet not a trace of inflammation in any part of the brain or its membranes was found after death, not even at the base, where some might have supposed it to have occurred. I have seen this inflammation exist, yet without convulsions or rigidity. I have seen slight delirium, and then profound coma, with no effusion in the ventricles. The case, also, which I have given you the morbid appearances of to-day, did not at all exemplify the symptoms we might have expected, had we been aware of what was going on in the brain.

In conclusion, I may remark that the fluctuations and variability in the symptoms of any one case will show you how difficult must be the satisfactorily connecting these variable symptoms with special and permanent lesions. As Dr. Bennet remarks, "the cerebral, the spinal, the circulatory, the respiratory, and the muscular systems all present the most remarkable fluctuations in their functions. The children are in a deep coma one day, and the next are easily roused, and perfectly conscious. The vomiting at one time is perpetually occurring, and at another the stomach shows no evidence of morbid irritability; the limbs are now convulsed, and now paralysed; the pulse for a few hours quick and intermitting; the face flushed one moment and pale the next, and so of all the more important functions."

A COURSE
OF
LECTURES ON SURGERY,
BY

SAMUEL COOPER, Esq., F.R.S.,

Professor of Surgery to University College, London;
Consulting Surgeon to London University Hospital, &c.

LECTURE XII.

In the treatment of mortification, three primary indications are concerned—1. To stop the progress of mortification. 2. To promote the separation of the dead part from the living. 3. To heal the wound, if an operation has been necessary, or otherwise the ulcer resulting from loss of substance.—These indications are common to all species of mortification. In fulfilling the first of these—in endeavouring to arrest the progress of mortification, supposing it to be acute—you will seek to remove the exciting cause. As I have already had occasion to dwell upon this point, I only mention it, important as it is here, as, indeed, in all other parts of surgery. But this exciting cause in a great number of cases has already ceased, and the surgeon has to deal with its results; under these circumstances the question arises—how far should you have recourse to antiphlogistic treatment?

Where mortification is evidently the result of inflammation—where inflammatory fever and an excited action of the bloodvessels surrounding the mortified part exist—a moderate antiphlogistic treatment is indicated. The excessive action of the sanguiferous system should be cautiously reduced by leeching, purgative, diaphoretic, diluent medicines, and abstinence from animal diet; but this treatment is only to be continued so long as the local inflammation and inflammatory fever exist concurrently with mortification, since by the mortification of any large portion of the body the system itself is greatly shocked, and rendered unable to stand against violent treatment. In such cases too much circumspection cannot be employed, since frequently, immediately upon the subsidence of the inflammatory fever, the patient sinks into a state of prostration and nervous agitation; and in every case there is more or less of weakness, and, if the system has been too much reduced, the consequences are likely to be disastrous.

After the abatement of the inflammatory or symptomatic fever, which usually takes place in the transition from gangrene to sphacelus, the opposite system of treatment must be pursued: stimulants, anodynes, and a more generous diet are to be given.

At one time, bark was regarded by the surgeons of this country as almost a specific in resisting the progress of this disorder; without denying, however, its usefulness in particular cases, this opinion is altogether untenable, and is now rejected by men of experience. So far from being valuable in all cases, its exhibition would frequently be very injurious. After the first stage of mortification, when the inflammation surrounding the mortified part has abated, it will often be advisable to employ it as a tonic, especially if the appetite is bad and the patient low; it should then be administered with wine and light diet. Also, where the constitutional disturbance is of the typhoid kind, bark and quinine may be useful. As stimulants, however, ammonia and wines—those of Spain or Madeira—are far preferable. Opium is, also, very serviceable where severe pain or nervous symptoms are present; the best forms of it are the muriate and acetate of morphia, and they should be given frequently in the day, in order to keep the constitution under their influence during the whole of the twenty-four hours.

Then, what local treatment is to be adopted for stopping the progress of mortification? You may hear of many applications which were resorted to thirty years ago, but which are scarcely at all used at the present day—as, for instance, the fermenting poultice,

praised in its day for its supposed antiseptic properties. Surgeons trust now more to common means, such as linseed poultices and fermentations. The French surgeons even now, I believe, use bark locally; our system, however, is more simple. Formerly it was the custom to make cuts in the sloughs, to allow the passage of turpentine and other strong preparations, not only into them, but through them to the healthy parts beneath; but, as it is obvious that as no application can restore the vitality and healthy condition of the slough, so also nothing but injury can come of irritation of the living flesh beneath and around. Of course, there can be no objection to the application of turpentine or chloruret of soda, with the view of checking the fetor which exhales from the slough; but beyond this use such applications can be of no benefit. Where sanious matter is lodging in or below a slough, a careful incision may be useful, to allow of its exit; but such incision should be through the dead part only. I attended a gentleman but a short time since, suffering from mortification, who complained of great pain, and imagined that there must be some fluid in the slough. I excised it, and a great quantity of ichorous matter escaped, to his great relief.

The second indication I named was to promote the separation of the slough. The means by which nature accomplishes this is a vital process, not to be explained on either chemical or mechanical principles, but depending on the increased action of the absorbent vessels. Although the slough is dead, and may be cut, pricked, or scratched, without pain and no functional connection exists, there remains the attachment of cohesion, from which it cannot forcibly be wrested without both pain and danger. As the vital action necessary to the separation of the dead and living parts can only exist in a degree proportioned to the vigor of the whole system, it is necessary that it should be maintained, as well as that local treatment should be resorted to. Where amputation is not strictly indicated, the parts should be left as much as possible to nature, only applying moist and emollient applications. In the derangement and prostration of the system always implied in mortification, a little violence will bring on an extension of the evil; and therefore, besides the use of the emollient poultice, with or without a solution of chloruret of soda, or with a small proportion of finely-powdered charcoal, it is to a general treatment that we are to look as the most efficient method of expediting the removal of the slough. Let the patient have the benefit of the fresh air; let his linen be frequently changed, and his chamber be well sprinkled with chloride of lime, and his constitution be supported in the manner I have described, and he will then be in the most favorable circumstances for losing the slough. Sometimes you will find one half of the slough healing much better after the other half has been cut away; and, as this proceeding involves no injury of living textures, it is, under some circumstances, advisable to adopt it. I ought to mention, that when a slough separates no hemorrhage generally takes place; the bloodvessels are loaded with coagulum; and this will explain why, when amputation in mortification is performed a little above the line of separation, there is often no hemorrhage of importance.

The third indication—to heal the ulcer, or wound if amputation has been necessary—need not be dwelt on, as it will be considered when we come to speak of the treatment of ulcers, wounds, and amputations.

ON THE PHYSICAL PHENOMENA OF
LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART V.

DIGESTION.

The existence and preservation of an animal are dependent upon the condition that certain substances, called *food* or *aliments*, be constantly

introduced into its body. These substances, mostly solid, undergo, in the digestive apparatus, a series of modifications, by means of which they are ultimately divided into excrementitious matter, which is expelled from the body, and nutritive matter, which intermixes with the blood, and is finally assimilated to this fluid. The ultimate end and purpose of digestion is the preservation of the integrity of the organism, by resupplying the blood constantly with those elements which it loses incessantly in the act of nutrition.

All alimentary substances may be divided, with respect to their chemical composition, into three most distinctly characterized classes: the first class comprises the neutral nitrogenous substances, viz., albumine, fibrine, caseine; the second contains the fatty matters; and the third, gum, starch, and sugar, substances the composition of which may be represented by water and carbon. Experience has proved that the alimentary substances of the second and third category do not in themselves suffice for the nutrition of animals, but that it is indispensable to adjoin to them those belonging to the first class.

With regard to the substances of the first class, we must briefly notice here the important discoveries of Mulder and Liebig. Albumine, fibrine, and caseine are of identical composition—all three contain eight equivalents of carbon to one of nitrogen, and seem to differ simply in the small quantity of phosphorus and sulphur which they respectively contain; after the removal of the two latter elements, there remains a principle in common to the three, to which Mulder has assigned the name "*protine*," and of which the formula, adopted by Liebig, is

We may, therefore, consider these substances, although differing greatly in their respective physical properties, as isomeric, and as simple modifications of *protine*. Dumas and Liebig have discovered, besides, that *vegetable albumen* is identical with *animal albumen*; that there exists in the flour of the cereals a substance analogous to caseine; and that a substance similar to animal fibrine is found in the *gluten*. Thus, there is no essential difference between the food of the herbivorous and that of the carnivorous animals, except that the former draw the elements of nutrition from plants, and the latter from other animals.

Now, as the composition of the blood, as well as of the greater number of animal tissues and fluids, is analogous to that of the neutral organic substances which we have just now mentioned, and as these substances, in becoming part of the animal organism, suffer no change of chemical composition, but undergo simply changes of form in the process of nutrition, it seems perfectly natural and correct to assume that the neutral nitrogenous substances are *simply dissolved*, in the act of digestion, to permit their passage to the blood, and that they join this fluid unaltered in every other respect.

The isomerism of these substances is likewise demonstrated by the fine discovery of Denis, i.e., that fibrine is converted into albumen when dissolved in a solution of nitrate of potash. This act is the more curious as this conversion occurs only with the fibrine of the venous blood; whilst that of the arterial blood does not dissolve in solution of nitre, nor change to albumen. Scherer put the fibrine of venous blood exposed to the action of oxygen, and found that the latter element was converted into carbonic acid, and that the fibrine lost thus the property of changing to albumen with solution of nitre.

Physiological experiments have proved long ago that the digestion of the alimentary substances of the first class is a purely physical act, and independent of the living organism. Every one knows the celebrated experiments of Spallanzani: flesh, gluten, coagulated albumen, were enclosed by that experimentalist in small perforated metallic tubes, which latter were then introduced into the stomach of an animal; it was subsequently found that these substances thus enclosed had been dissolved, just as they would

have been if introduced into the stomach in the usual manner. We shall see hereafter that this solution is effected by one of those catalytic actions mentioned in Part I.

The recent experiments of Melsens, and more particularly those of Bernard and Barreswil, have shown that the gastric juice contains a free acid (according to them, lactic acid), and that it holds in solution a peculiar substance called *pepsine*, which chemists have succeeded to isolate in a sufficiently pure state; it is this same substance that Payen has lately studied, and to which he has given the name *gastase*. The acidity of the gastric juice is greater or less according to the nature of the aliments: in the empty stomach the acidity is less pronounced, but it becomes more marked upon the introduction of food, and is most decided if this food happens to consist of fibrine, albumen, &c. Pepsine effects the solution of fibrine, albumen, &c., by catalysis. This may be readily demonstrated. Take an infusion of pepsine, acidulate it with a few drops of hydrochloric acid, and expose fibrine or coagulated albumen to its action for about twelve hours at a temperature of 30° (86° Fahrenheit), complete solution will ensue. By neutralizing the acid and evaporating the solution, you may subsequently reproduce the fibrine and albumen unaltered. The acid solution of pepsine (or the gastric juice) is secreted in the stomach alone, or by certain glands situated in the mucous membrane of that organ. The catalytic property with which pepsine is endowed requires, for its manifestation, invariably the presence of a free acid, mineral or organic. We shall hereafter see how much the catalytic action of this substance is modified by its solution in an alkaline fluid. Pepsine loses its properties, and becomes insoluble, if heated beyond 50° (122° Fahrenheit).

The neutral nitrogenous substances dissolved in the stomach by the acid fluid, or by the catalytic action of the pepsine, find their way to the blood by the simple imbibition of the wall of the capillary bloodvessels of the stomach; coloured water, and coloured alcoholic drinks, introduced into the stomach, are likewise absorbed by the capillaries of this organ: they do not pass beyond it, are not found in the chyle and yet arrive in the blood. Bouchardat and San-draw fed animals with fibrine coloured with saffron or cochineal; the chyle was subsequently examined, but the colouring matter was not found in it. These physiologists have made a still more conclusive experiment: they fed some animals upon fibrine, and kept some others altogether without food for some time; the whole of the animals were then killed. The chyle are found to be identical in all, nor did the matter found in the intestines present any differences; a portion of the fibrine was found imperfectly dissolved in the stomach of those animals that had been fed upon this substance. The celebrated experiments of Tiedemann and Gmelin have likewise proved that the amount of fibrine found in the lymph and chyle, after a long fast, is not smaller than that found in these fluids after digestion. Coagulated albumen, gluten, or caseous matter yield the same results in this respect as fibrine.

The motion of the walls of the stomach promotes the action of the pepsine upon the food, as all agitation tends to aid the action of two liquids upon one another, or the solution of a solid in a liquid. This motion facilitates, moreover, the absorption of the liquid portion of the contents of the stomach, by changing incessantly the points of contact between them and the internal surface of the organ. The disorders in the digestive process, supervening upon the section of the nerves of the eighth pair, are to be partly attributed to the cessation of these movements, which most certainly are subject to the action of these nerves; their section carries, moreover, great perturbation into other functions, that are indispensable for the integrity of the animal economy.

We come now to the digestion of amylaceous matter. Sandras and Bouchardat's experiments have considerably enlightened us upon

this subject. These physiologists found that a few drops of pancreatic juice (of alkaline reaction), added to a certain quantity of starch paste, at a temperature of 35° to 40° (95° to 104° Fahrenheit), dissolve the paste speedily. The liquid becomes transparent, and it is subsequently found that every trace of starch has disappeared (this substance being converted into dextrose, or sugar).

The same effect is produced if some portion of the pancreas of the pigeon or of some other animal is used, instead of the pancreatic juice. Thus it would appear that the pancreatic juice and, perhaps, saliva likewise, as Magendie pretends, contains a substance which acts upon starch like diastase.

It is singular that this action should require for its manifestation the presence of a free alkali. If the pancreatic juice is made acid, it ceases to act upon starch, and, according to Bernard and Barreswil, acquires the property of acting upon neutral nitrogenous substances.

Do the dextrose and sugar, into which the starch has been thus converted by the action of the saliva and the pancreatic juice, pass directly to the blood, or are they first converted into lactic acid?

It is only in the blood of some diabetics that sugar has been found; the supposition that there is a further conversion into lactic acid seems to be more in accordance with facts. We must not forget here the important discovery made by Fremy, that certain animal membranes, when kept in water for some time, acquire the property of converting large quantities of sugar into lactic acid.

These same nitrogenous substances, which in a certain state possess the faculty to excite lactic fermentation, lose this property in another state, which may be termed "a state of more advanced transformation" (although we are as yet utterly in the dark regarding its nature); in this state their action is found to promote the conversion of sugar into carbonic acid and alcohol. We know, moreover, that a solution of sugar injected into the veins of an animal is speedily discovered in the urine.

We may, therefore, in accordance with the known facts of organic chemistry, and, resting upon the well-known results of the simple play of catalytic action, conclude that starch may be converted in the intestines into lactic acid, passing most probably first through the intermediate state of dextrose and sugar.

It would not be by any means absurd, nor in opposition to what is known at present regarding the process of digestion, to imagine that a portion of the sugar into which the starch has been converted, not simply undergoes lactic fermentation in the intestines, but suffers, besides, some other transformation analogous to that in which the infusory animals originate.

The recent experiments of Gruby and Delafond have proved beyond doubt that great numbers of these animalcules are found more especially in the stomach of the herbivorous animals.

A few words on the cause of diabetes, and the remedies employed against that disease, will not be out of place here.

Bouchardat was the first who gave it as his opinion that, in diabetes, starch is converted into sugar in the intestines, and passes in this state into the blood, and finally into the urine. This opinion has since been generally adopted.

Total abstinence from amylaceous food was consequently resorted to as the most efficacious means to effect the cure of this disease; the food of the patient was made to consist principally of neutral nitrogenous substances. There are some cases on record which would show that this treatment proved successful.

But, on the other hand, we have the numerous experiments of Dr. Capezzuoli, tending to prove that the quantity of sugar found in the urine of diabetic patients keeps no proportion whatever with that of the starch in the aliments; and that, even under the influence of an alimentation entirely consisting of neutral nitrogenous sub-

stances, the urine was found to contain the same quantity of sugar as during a farinaceous alimentation.

Dr. Capezzuoli found sugar in the faces of diabetic patients, and in the matters vomited by them, but only after a repast composed of amylaceous substances; the quantity of sugar found in these matters, however, was the same in the case of a healthy individual as in that of a patient labouring under diabetes. The fact thus revealed by Dr. Capezzuoli's researches is, at all events, of great importance for the theory of digestion, since it proves experimentally the actual transformation of the starch into sugar, supposed to take place in the intestines.

Finally, Dr. Capezzuoli has detected traces of sugar in the blood, and the purulent matter of an abscess, of a diabetic patient. It remains still to be explained, therefore, whence arise these abundant productions of grape-sugar in certain diseases that are attended with great emaciation.

We come now, finally, to the digestion of the fatty matters which arrive in such considerable quantity in the stomach of the carnivora, and are carried almost unaltered to the adipose tissue of these animals. A few words on the important question of the origin of fat in the herbivora, which has been considerably agitated of late by several distinguished chemists, will not be out of place here. Liebig maintains that the fat owes its origin to a transformation of the starch, this substance losing a portion of its oxygen, which is expelled from the organism in combination with carbon. Dumas, Boussingault, and Payen, on the contrary, maintain that the amount of fatty matter that exists in hay, beetroot, and straw, suffices to account for that which is found in animals fed upon these substances. Boussingault has demonstrated the correctness of this assertion by actual observation and experiment. He found 1113 grammes of fatty matter in the milk of a cow (placed in conditions suitable for the purposes of the experiment) during a certain period of time, whilst the fatty matter contained in the food taken by the animal in the same period of time amounted to 1614 grammes—leaving thus an excess of 201 grammes in favour of the food.

But the same physiologist has, on the other hand, proved, by experiments upon pigs and geese, that a larger quantity of fatty matter is generated in these animals than is contained in their food. Persoz has arrived at the same result.

It cannot be denied, therefore, that the animal economy possesses the faculty of transforming into fat a portion of the alimentary substances. Our chemical knowledge does not enable us to account for this transformation.

On the other hand, we have a great number of physiological observations tending to prove that animals fed upon fatty substances yield a chyle more abundant and milky than is usually the case, and from which the same matters may be extracted again upon which the animals have been fed; microscopic examination of these matters detects the presence of minute globules of fat.

The experiments of Sandras and Bouchardat have removed all doubt upon this point. These chemists fed animals upon sweet-almond oil, which was subsequently found in the chyle; the same result was obtained with suet. With bees' wax, the result was less complete, only a small quantity of that substance being detected in the chyle; this quantity became more considerable, however, upon introducing the wax dissolved in oil.

The same chemists have examined the matters contained in the stomach and intestines of animals fed exclusively upon fat: they found in the stomach a considerable portion of fat, solid at a low temperature, floating in the midst of a highly acid fluid, and in the intestines (both the large and the small) a species of thick pap which yielded a considerable quantity of fat upon being subjected to the action of ether.

From these facts, which the author also has verified by actual experiment, it seems to result that the fatty matters undergo no modi-

fication in the stomach, and pass into the intestines unaltered, except inasmuch as they are liquefied, or nearly so, by the heat of the stomach; the correctness of this view is, moreover, confirmed by the circumstance that gastric juice, when made to act upon a fatty substance out of the stomach, seems to operate no change whatever. The alkali of the bile and pancreatic juice saturates in the intestines the free acid of the gastric juice: this is another proof that the dissolving action upon neutral nitrogenous substances ceases in the intestines. It is not so easy to trace with precision, with the aid of analogies deduced from chemical facts, what becomes of the fatty matters after their exit from the stomach. This much is certain, however, that they are absorbed in the intestines, and that the chyliferous vessels or lacteals may be considered as almost exclusively charged with this function.

The author has made some experiments with a view to dispel the obscurity that reigns upon this branch of digestion. In one of these experiments, he heated a solution of 1.30 gramme (about 20 or 21 grains) of caustic potash in 300 grammes of distilled water, (a) in the sand-bath, to 35° to 40° (95° to 104° Fahrenheit); he then added a few drops of olive-oil to a portion of this solution, and agitated the mixture, which thereupon turned immediately milky—indeed, so much so that it might readily have been mistaken for real milk. Left to itself, the fluid continued to preserve this analogy with milk: it separated into two layers, of which the upper one was more opaque than the lower, and contained evidently minute globules of fatty matter. The author then filled a piece of intestine with this species of emulsion, and immersed it in the potash solution, maintaining the latter at a temperature of from 95° to 104° Fahrenheit. After the lapse of some time, the solution began to exhibit the characteristics of the emulsion within the intestine, and it seemed evident that a portion of the latter had passed through the membrane and mixed with the solution.

In another experiment, the author seems to have obtained still more conclusive results, tending to prove the existence of an endosmotic action between the emulsion and the alkaline solution.

The lacteals, terminating in close extremities, enveloped by the mucous membranes of the intestines, are filled (more particularly before feeding) with an alkaline fluid very analogous to lymph. After digestion (especially when the animal has been fed upon fatty substances), the liquid in the lacteals is found to have undergone no change, except inasmuch as it contains more fatty corpuscles, which impart to it a milky appearance. It is perfectly natural to assume that the same chemical affinity which produces the milky liquid in the mixture of the alkaline solution and the oil, acts likewise through the membrane of the lacteals.

The phenomenon of endosmosis, just now described, may be admitted among the causes of the absorption operated by the lacteals. This much is certain, that this absorption, *physically*, could not take place if the internal walls of the intestines were not bathed by a liquid possessing affinity for the fatty substances. How much the alkaline state of the liquid bathing the walls of the intestines promotes this absorption of a fatty substance may be readily demonstrated by the following simple experiment:—Fill two funnels with an equal amount of sand; pour pure water upon the sand in the one, and an alkaline solution upon that in the other; allow the liquids to run off, and pour afterwards an equal amount of oil upon the sand in the two funnels, and you will see the oil remaining for several hours on the surface of the sand imbedded with water, whilst, on the contrary, it will speedily disappear from the surface of the other, being imbibed by the sand impregnated with the alkaline solution.

(a) This solution is but slightly alkaline, and certainly less so than the lymph and chyle.

The neutral nitrogenous substances which, after their solution by the gastric juice, pass into the blood would speedily destroy the neutral slightly alkaline state of this fluid, which is necessary for the preservation of its properties; but the alkali of the chyle, lymph, bile, and pancreatic juice preserves this neutrality of the blood.

The chyle and the lymph hold in suspension a great number of minute granular bodies of from the one to the two thousandth part of a line in diameter, and which appear to consist of a fatty matter enveloped by a membrane, which latter, we have every reason to believe, is formed of a substance analogous to proteine. These same granulations are found in the yolk of eggs, in the milk, chyle, lymph, and in all the liquids that exude in pathological cases, or are destined for new formations. These elementary granulations have been observed to unite to globules or cells analogous to those of the blood, and have, on that account, been looked upon as the morphological elements of all animal tissues. Donné has recently observed that, when milk is injected into bloodvessels, the globules of the milk disappear after the lapse of some time, being covered with an albuminous layer in form of a vesicle; they then assume the appearance of the white globules of the blood, which, at last, disappear likewise, being probably transformed into red globules; the blood presents finally the same appearance which it had before the injection of the milk.

Thus it would seem that the organic element consists simply of a vesicle, constituted by layer of albuminous matter, which collects a granule itself around a nucleus formed principally of fatty matter. The following important experiment, made by Ascherson, may be readily repeated:—Place a few drops of oil into contact with albumen; the latter substance will immediately coagulate; mix the whole together, and examine a drop of the mixture under a microscope; you will see a group of vesicles, each of the consisting of a minute globule of fat enveloped by an albuminous membrane, which is, in sort, coagulated; it will appear to you as if you had real adipose cells under the microscope. The fact may be observed still more distinctly by placing upon a glass plate a drop of oil and drop of albumen side by side, and effecting slowly and gradually the contact of the two; is curious to observe, under the microscope, the almost instantaneous formation of an exceedingly delicate elastic membrane, which is speedily covered with numerous folds. Ascherson has shown that this formation, operated by the oil and albumen, is really of cellular nature. He added a little drop of water to a drop of this formation; the result was swelling of the cells and emission of minute particles of oil. Upon using solution of acetic acid instead of water, the cells seemed to swell to bursting; in oil, on the contrary, they seemed compressed and decreased in volume. These facts, which it would be desirable to extend by further observations, belong evidently to the phenomenon of endosmosis, and can be comprehended only by admitting cellular formation. Thus, we see here a physico-chemical operation, leading to the discovery of the mechanism of the formation of elementary granulations. Fatty substances and compounds of proteine are constantly introduced into the organism; they are found in all animal fluids; the globules of fat which penetrate into the chyliferous tubes, and are thus placed in the midst of an albuminous liquid, must speedily get enveloped by analogous membranes, and must, for this reason, form vesicles similar to those which microscopic observation discovers in the chyle, lymph, and blood.

Now, in conclusion, a few words on the gases of the stomach and the intestines, and also on the inorganic bodies which form, more or less directly, an integral part of the animal organism.

Observation has proved that oxygen is hardly ever found among the gases of the stomach, and still less of the intestines; the principal gases met with in these cavities are nitrogen, carbonic,

acid, a certain amount of carburetted hydrogen, and sometimes traces of sulphuretted hydrogen. A large quantity of atmospheric air is evidently introduced into the stomach, being, as it were, *swallowed* with the food. The oxygen of the air disappears in the stomach, passing, perhaps, through the membranes by a sort of gaseous endosmosis, and finding thence its way to the blood; or, what is more probable still, taking part in the modifications that tend, as we know, to transform the nitrogenous albuminous substances into ferment (yeast). Carbonic acid seems to be abundantly evolved in this process; in some ruminants, fed upon fresh and moist herbs, the disengagement of carbonic acid is stated to be enormous. The production and disappearance of this abundant quantity of gas in the stomach and intestines take place and succeed one another at times with amazing rapidity. The presence of the hydrogen we are as yet unable to connect with any of the physico-chemical changes observed in the process of digestion.

The author has found by experiments that the oxygen is not necessary, as Liebig appears to suppose, to aid the dissolving action of the gastric juice upon fibrine and coagulated albumen. A piece of the stomach of a pig was placed in slightly acidulated water, together with some fibrine and coagulated albumen; the water had been previously boiled for several hours so as to expel every trace of air, and was subsequently, after the above-mentioned substances had been introduced, protected from the access of air by a thick layer of oil; the fibrine and albumen were dissolved as completely in this liquid as they were in an analogous fluid left in free contact with the air.

The inorganic substances found in the organism have been evidently introduced with the food; they cannot force their way to the blood if they are not soluble in water or in the gastric juice of the stomach. All matters insoluble in these menstrua are necessarily rejected with the excrements. Physicians never lose sight of this fact in the selection and preparation of remedies. We know at present, by experience, that the perfect inefficiency of large doses of certain inorganic salts, which at one time created great astonishment, is quite natural; these salts, being insoluble in water and in the gastric juice, are rejected unaltered with the excrements.

ORIGINAL CONTRIBUTIONS.

NEW MODE OF DISTINGUISHING THE SPOTS OF ARSENIC AND ANTIMONY.

By WILLIAM A. GUY, M.B.,

Professor of Forensic Medicine, King's College, &c.

A simple, expeditious, and certain means of distinguishing the spots of arsenic and antimony, obtained by the use of Marsh's apparatus, has appeared to me so desirable that I have made many experiments with a view to discover a means; but, as often happens in these cases, the true method was the last to present itself. Lassaigne has proposed to employ the pour of iodine, or an alcoholic solution of lime, followed in succession by sulphuretted hydrogen and ammonia, for that purpose, and more recently M. Cotterreau, jun., has suggested the use of the vapour of phosphorus; but these methods are tedious, and open to some objections which seriously impair their value. The following plan is simple, expeditious, and decisive:—Having obtained a crust of metal on porcelain (the cover of a porcelain crucible is very convenient for the purpose), treat it with a drop of hydrosulphuret of ammonia. The antimonial stain is rapidly dissolved, the thin portions of the crust at the circumference instantaneously, while the centre of the crust speedily contracts, and in less than a minute disappears. The arsenical stain is at first scarcely affected at all, but after a considerable interval of time, varying with the

thickness of the crust, is also acted upon, but imperfectly. On the evaporation of the hydrosulphuret of ammonia the antimonial spot assumes the form of a distinct orange-red sulphuret of antimony, without any trace of the metal; while the arsenical stain, unless the test be repeatedly applied, always presents a centre of metal, with a border of pale lemon-yellow sesquisulphuret. If treated with a drop of liq. ammonia this latter stain disappears, while the antimony remains intact; and, on the other hand, on touching the spots with muriatic acid the antimony disappears and the arsenic remains.

The best way to prove the delicacy of this test is to compare a small thin stain of arsenic with a large and thick spot of antimony. It will be found to act characteristically even in this extreme case, the difference being very striking in point both of time and of intensity of action.

With this subsidiary test of hydrosulphuret of ammonia, Marsh's test resumes the superiority for delicacy, simplicity, and certainty, of which Reinsch's test threatened to deprive it. Those who are in the habit of employing both these tests will, I think, admit that Marsh's apparatus is more easy of application than Reinsch's test; the successive processes of boiling the slip of copper in the suspected liquid acidulated with muriatic acid, and obtaining distinct octohedral crystals of arsenious acid, occupying more time and being more difficult than the use of Marsh's apparatus in any of its forms, while it is obviously much easier to obtain the metal and identify it by hydrosulphuret of ammonia than to procure well-marked octohedral crystals of arsenious acid.

A metallic spot obtained by the use of Marsh's apparatus (the purity of the sulphuric acid and zinc having been previously ascertained), undergoing a slow and imperfect conversion into a pale lemon-yellow circle bordering a centre of metal, this border readily soluble in ammonia, but insoluble in muriatic acid, is most certainly arsenical. On the other hand, a metallic spot obtained with like precautions, disappearing almost instantly when touched with hydrosulphuret of ammonia, leaving a distinct orange-red spot, soluble in muriatic acid, but insoluble in ammonia, is as certainly due to antimony.

The coppery hue of the arsenical crust, and the smoky appearance of the antimonial crust, will in many instances serve as a distinction; but, as these appearances are not quite uniform, I do not insist upon them.

The hydrosulphuret of ammonia must contain an excess of sulphur, for otherwise the test will fail. When recently-formed hydrosulphuret containing an excess of ammonia is used, there is no material difference in the effect on the two stains, but on the addition of sulphur the test acts characteristically. I should, therefore, recommend that, whether we employ the hydrosulphuret recently formed, or as it is commonly found on the shelves of the laboratory, we should always add to it a portion of sulphur. When so prepared, the largest and thickest stains of antimony will be found to disappear in from three to seven seconds, as I have ascertained by the watch, while even the faintest arsenical stains remain for a very considerable period intact, and are never completely dissolved by a single application of the test.

15, Bloomsbury-square, July 6, 1817.

ADDITIONAL OBSERVATIONS. Since writing the above, I have made a great number of comparative experiments, which have, in most points, confirmed the results first obtained. The antimony is in all cases rapidly removed, the arsenic slowly, and generally imperfectly; but when a considerable excess of sulphur is employed the arsenic is at length completely dissolved, and the stain, instead of presenting a centre of metal with a border of pale yellow sesquisulphuret, consists of a white centre, with a yellow border. The pale-yellow border of sesquisulphuret of arsenic surrounding a centre of imperfectly dissolved metal, or a white centre, as

just described, contrasts very strongly with the orange-yellow sulphuret of antimony, which generally forms a stain of uniform colour. Occasionally, however, when the hydrosulphuret contains a great excess of sulphur, and is used in large quantity, the antimony stain also presents a white centre with an orange border; but in any case the colour of the border of the crusts is highly characteristic. This white centre presents in either case an imperfect crystalline texture, and probably consists of the pentasulphurets of arsenic and antimony. The only precautions which it appears necessary to point out are—1. To employ a quantity of hydrosulphuret proportioned to the size of the crust of metal. A single drop applied by the point of a glass rod, proportioned to the size of the crust, is sufficient for the purpose. If a larger quantity is used the colour of the sesquisulphuret is not so well marked; and 2. Not to use hydrosulphuret of ammonia containing a large excess of sulphur. The sulphur should not be added to the test in such quantity as to give it an orange colour.

The value of the several tests which have been proposed for distinguishing the crusts of arsenic and antimony having been called in question, I have been induced to repeat them with care, and have satisfied myself that there are no tests in use among toxicologists which give more striking or satisfactory results. Of all the means of discrimination which have been suggested, a solution of the chloride of lime, as recommended by Bichhoff, gives, perhaps, the most striking result. The crust of arsenic, when touched with a drop of this solution, immediately and entirely disappears, while the spot of antimony is not affected by remaining for hours or days immersed in it. The spirituous solution of iodine acts almost equally characteristically, by removing the arsenic stain immediately, but the spot of antimony very slowly. The test proposed by M. Cottereau, jun., is only less satisfactory, because it occupies more time. The arsenic spot disappears after a few hours of exposure to the vapours of phosphorus, at the temperature of the air, while the stain of antimony resists its effects for several days. This last test has also this advantage, that by exposing the spot on which the arsenic was deposited to sulphuretted hydrogen, a sesquisulphuret of arsenic is formed which can be readily identified by its colour and solubility in ammonia. Any one of these tests applied with proper precautions will furnish a perfectly safe means of discrimination. The one which I have ventured to propose has the advantage not only of presenting within a short space of time a series of characteristic differences, but of confirming the indications of the other tests by an action the exact reverse of theirs: for the chloride of lime, the spirituous solution of iodine, and the vapours of phosphorus act rapidly on the crust of arsenic, and slowly and imperfectly on that of antimony; while the hydrosulphuret of ammonia acts promptly on the antimony, but slowly and sparingly on the arsenic.

ON THE CAUSE OF THE RECENT EXPLOSION OF GUN-COTTON.

By H. LETHBRIDGE, M.B.,
Lecturer on Chemistry at the London Hospital.

I am tempted to record the result of a few experiments, which I have made with gun-cotton, with the view of ascertaining whether it can be rammed, or otherwise compressed, into a case or chamber, without risk of explosion.

These experiments were set on foot by reason of the recent accident at the congrève-rocket manufactory at West Ham, in Essex, whereby three lives were lost, and much other damage done.

It appears that the Messrs. Wade, the proprietors of the above-mentioned factory, had been endeavouring to construct rockets of gun-cotton, equal to a 12 lb. congrève; but, forejudging that there might be some danger in the attempt, they deemed it necessary to use every precaution which presented itself: in the first

place, to employ a gun-cotton which was not more than one third the ordinary strength; and, in the second place, to subject it to a few severe tests, by way of knowing whether it was liable to explosion from friction or percussion. Portions of it, therefore, were placed on an anvil, and struck repeatedly with a hammer of about seven pounds in weight, but it did not fire. It was then mixed with sand, and afterwards with gunpowder, and again struck, but in every case it failed to explode. After this they rammed a few small one-pound rocket cases, by means of a mallet and drift; still it did not explode. Considering, therefore, that the material might be used in a larger rocket-case with safety, they proceeded to construct one which should be equal to a twelve-pound congrève. Four men were employed in the work; they used the ordinary rocket-case, which is eighteen inches long, and two and a half inches in diameter; it is made of sheet iron, and lined with paper; through the centre of the case a gun-metal spindle passes, which is ten inches long, and tapering from two inches in diameter at the lower end, to one inch at the upper; the whole is secured firmly in a block of wood. It was rammed by means of a wood drift, or rammer, aimed with a copper ferrule, and driven by a gun-metal monkey of thirty-six pounds weight, falling from a height of ten feet. The cotton was introduced into the case in charges of one ounce; each had been previously compressed by a weight of three tons; each charge received forty blows from the monkey, and to guard, as the proprietors supposed, against any chance of overheating from friction, they were requested to strike slowly, and to wait between the blows. In this way they had proceeded as far as the twenty-fifth charge, giving it in all 1190 blows, when the foreman left the building, directing them to give it ten blows more, so as to make up the 2000, and then it would be finished. It appears, however, from the testimony of one of the men, who lived for twenty-four hours after the accident, that on giving it the 1191st blow the rocket exploded with fearful violence; the gable end of the house was blown out; the wood safety partitions, which had stood many an explosion from gunpowder, were destroyed, and the two men who were working at the monkey were driven with the partition of the house into a ditch about two feet distant; one was killed on the spot, the other died about twenty-four hours afterwards, while the poor fellow who attended to the charging was shattered in a dreadful manner, and must have died instantly. It does not appear that the explosion was attended by much noise, for the inhabitants of the village close by did not perceive it.

Having gone over these particulars, I was called upon by the coroner to state my opinion as to the probable cause of the accident; and I could not believe but that it arose from the friction produced either by the drift on the hard-rammed cotton, or else from the cotton against the case or spindle.

In the course of the inquiry, it was stated by Messrs. Hall, the patentees, that a similar accident had happened with them when they used the monkey to pack the cotton, and they attributed it, as they did the present accident also, to the heat evolved by the sudden compression of the air. A little reflection, however, will show that such could not have happened here, for, to say nothing of the pressure to which the cotton had been previously subjected, and the consequent liberation of nearly all the air between its fibres, it had received nearly 2000 blows from the monkey, which would have been sufficient either to explode it much earlier in the work, or to have driven out all the air from its texture. I believe, therefore, in the former view of the case; and, in order to put this conclusion to the test of experiment, I have been occupied in subjecting gun-cotton of ordinary composition to pressure, from various sources. It was found that there was no difficulty whatever in firing gun-cotton, by striking it smartly with a hammer, and that it would also explode whenever it

was driven by blows into a metal case; but I found that it could be compressed with safety into its smallest bulk, provided the pressure was used slowly and steadily, as, for example, by means of a screw or lever; in this way 100 grains of it could be compressed into the space of one cubic inch.

5, Goswell-road, June 6.

CONTRIBUTIONS TO THE MEDICAL TOPOGRAPHY OF THE MEDITERRANEAN.

By WILLIAM THOMPSON KAY, Esq., Assistant-Surgeon of the Plymouth Division of Royal Marines.

"THE GRAND OBJECT OF ALL TRAVELLING IS TO SEE THE SHORES OF THE MEDITERRANEAN: ON THESE SHORES WERE THE FOUR GREAT EMPIRES OF THE WORLD—THE ASSYRIAN, THE PERSIAN, THE GREEK, AND THE ROMAN. ALL OUR RELIGION, ALMOST ALL OUR LAWS, ALMOST ALL THAT SETS US ABOVE SAVAGES, HAS COME TO US FROM THE SHORES OF THE MEDITERRANEAN."—Samuel Johnson.

SYRIA.—Its Situation, Name, Extent; Divisions, Ancient and Modern; Physical Characters; Productive Industry; Manufactures; Civil and Social State; Climate; Diseases; State of Medicine and Surgery; Works on the Topography, Natural History, &c., of Syria.

(Continued from p. 292.)

ZOOLOGY.—The object of the present paper is to afford a succinct outline of the zoological distribution of Syria, rather than a lengthened dissertation; and therefore, where any species is omitted, it has been intentionally done for the sake of brevity.

Those marked thus * are found in Syria generally, and are also to be considered as belonging particularly to that country; whilst those marked thus ** are found only in the neighbourhood of Beirut.

DIVISION I.—VERTEBRATA.

CLASS I. MAMMALIA.—ORDER I. BIRMANIA. —Genus Homo, CAUCASIAN RACE.—Syrian Division.

This is the Syro-Arabian race of Pritchard; the Leuco-Syri of Herodotus; and the Semitic of Biehler and other German writers. As the peculiar characters of this race are well known, I shall not occupy the space of this journal by describing them, but give the Arabian estimate of female beauty, as being more interesting and less known:—

"Four things in a woman should be black—the hair, the eyebrows, the eyelashes, and the iris of the eyes; four white—the complexion, the white of the eyes, the teeth, and legs; four red—the tongue, the lips, the middle of the cheeks, and the gums; four long—the back, the fingers, the arms, and the legs; four round—the head, the neck, the arms, and the ankles; four wide—the forehead, the eyes, the bosom, and the hips; four delicate—the nose, the eyebrows, the lips, and the fingers; four ample—the lower part of the back, the thighs, the calves of the legs, and the knees; four small—the ears, the breasts, the hands, and the feet."

(To be continued.)

ON THE DIRECTION OF PLANTS.

By Professor MACAIRE, of Geneva.

ABSTRACT.

This paper is divided into three paragraphs. The first has for its object some observations and experiments on the curling of the tendrils of the *amus communis*. After the description of the tendril, which in this plant is the footstalk of an abortive leaf, the author shows that the contractile power of the organ is excited by contact with any object whatsoever, even another part of the same plant; that the curling begins at the point of contact, but continues on both ends of the tendril, either to tie knots, if there is something to embrace, or to take the shape of a corkscrew, if not. In a few minutes the knots are formed, and exercise a sort of pressure; a separation from the plant stops the continuation of the curling up of the tendril.

The curling always takes place in the same direction from outside inwards. Plunged in water, or in a solution of gum, the tendril does not contract itself, but does not lose the faculty of curling up by contact with a solid body. Ammonia, alcohol, eau de Cologne, have little or no effect.

Diluted acids, sulphuric and nitric even the vapours of this last, without actual contact—excite immediately an energetic contraction in the tendril. It is the same with a solution of sublimated corrosive.

On the contrary, prussic acid stops the curling up already begun, and renders the tendril incapable of being any more excited by the contact of a solid body. The conclusions of the author on this head are, that the contraction of tendrils cannot be explained by the hypotheses of Knight and De Caidolle, of an unequal action of light on the two sides being too rapid for so slow a process, and that it is a vital property residing in the organ on which the poisons act as they do on the sensitive plants.

The second paragraph is on the direction of stems towards the light. After having mentioned the nature of the phenomenon, and the explanation proposed by De Caidolle—viz., the bending of the stem by an accumulation of carbon, and consequent hardening of the lightest side—the author

tries to ascertain if the light exercises on the green parts of plants a real attraction.

He operated on naturally floating plants—duckweed, *lenna minor*, and *polyrhiza*, and on different species of other plants placed on cork floaters. He placed them all on water, in vases which were partly darkened by screens, and never saw the plants receiving from the light an impulsion which brought the floaters away from the place they had been put in. When the plants fully developed were kept in the dark part of the vase, they sprouted from the neck of the root a new stem, slender and blanched, that ran all along the water to reach the diaphragm, and then gave out leaves and grew erect; but the floater never was attracted towards light, though this new stem was often three feet long and more.

In the course of these experiments he had occasion to notice the tendency of roots when developed in the light to take a spiral shape, and found that the white light seems to favour the production of radicular fibrils, while, on the contrary, the blue light hinders it.

In examining the grounds of Dutrochet's theory on the existence in stems of two systems of cells and fibres, decreasing in size from the circumference to the centre, or *vice versa*, by which he explains by endosmose the bending of the stem, the author has found that this bending in contrary directions of the two parts of a stem slit longitudinally has nothing to do with light. In cutting the stem in various directions it always bends outwards by the swelling of the cells and the resistance of the cuticle, and does not bend at all if this last is removed or slit in two or three places.

To ascertain if the sap could be supposed to march by endosmose from cell to cell, he has placed within one another three endosmose tubes filled with a solution of sugar, the last and largest plunging in water. It was the only one in which any endosmose was visible, the difference in density with the others being insufficient to produce it. It is probable that it would be the same for the cells of plants; and some facts have induced him to think that the liquids penetrate chiefly through the intercellular spaces of the vegetable tissue.

The author has assured himself by experiments that neither heat nor light has any influence to increase the quantity or the rapidity of endosmose, and in consequence is little inclined to admit this phenomenon as exercising the influence sometimes attributed to it in vegetation, and especially in the direction of the stems towards light.

The third paragraph concerns the direction of leaves. After having described the appearance and structure of the two surfaces of the leaves, and mentioned the known fact of the direction of the superior or varnished surface towards the light, the author reviews the labours of Bonnet and Dutrochet on that subject. As no direct experiments had proved that the direction of leaves was due to the influence of light itself, he has begun by showing—1. That the turning over of inverted leaves did not take place in complete obscurity. 2. That it was possible to induce a leaf to turn itself over by screening its superior surface, and by lighting its inferior one with an inclined mirror. 3. That when both the surfaces of the leaf were lighted, the leaf took a globular form so as to protect against light the inferior surface.

He shows afterwards that, though in most plants the turning over of inverted leaves takes place through a movement of the footstalk, yet in some of them it is the flat part of the leaf that curls itself over, and that in all the same thing happens when it is the best way to bring back the superior surface of the leaf towards the light. This is the case, for instance, when the footstalk has been removed, and when the superior surface is screened by a piece of black paper fixed to it, and the inferior one lighted by a mirror. The flat part of the leaf bends its edges, and takes a globular form.

The two faces of the leaf do not seem to be acted upon by any real attraction towards the

light, for when placed in an inverted position, on movable floaters, it turns over by means of the footstalk or the flat part, without creating any motion in the floater.

The removal of one or many leaflets in a compound leaf, or of part of a single leaf, does not prevent the turning over of the remainder when placed towards the light in an inverted position.

By means of coloured glasses, whose purity of light had been ascertained by the prism, it has been shown that the leaves turned over best in the blue rays, next in the violet, but not at all in the red.

The author next examines the difference produced according as the light shone on one or other of the surfaces of leaves, on their power of exhalation and decomposition of carbonic acid. To measure the exhalation, he placed in a bottle full of water, whose weight was known, a leaf with one of the surfaces darkened, and the other exposed to light, changing the surfaces alternately during the same time. The result of a great many series of experiments has been to show that the loss of water by exhalation, in all temperatures and by all weather, is much more considerable in the same time when the inferior surface of the leaf is exposed to light than when it is the superior. This increase explains the rapid withering and subsequent death of inverted leaves which cannot turn themselves over.

In coloured glasses the blue rays have caused the greatest exhalation; next, the diffused white light; next, the green; the last are the red rays. In examining under the same circumstances the decomposition of carbonic acid, the author has first sought in what part of the leaf this chemical power resided. He found that the green matter did not possess it by itself, that it is operated in the cells of the parenchyma, and that the vessels and pores of the cuticle have a useful influence in the phenomenon, so as to increase the quantity of oxygen disengaged.

When solar light is received on the superior surface of leaves plunged in spring water, the quantity of oxygen gas disengaged is, in the same time and under similar circumstances, two or three times greater than when it is received on the inferior surface. The same difference may be observed in the diffused light by means of the leaves of the *camellia japonica*, which, when kept during some time in the dark in spring water, give up, when in the light, bubbles of oxygen gas through the central vessels of the footstalks.

In recapitulating the facts which the author has attempted to prove in this paper, it shows—

1. That the theories advanced to explain the curling up of tendrils do not agree with the experiments made on those of the *tamus communis*, and that it is the result of a vital irritability acted upon by chemical agents.
2. That the direction of the green parts of plants towards light is not the result of an attraction, properly so called.
3. That the bending outwards of slit stems is due to the elongation of the cellular tissue by endosmose of water, and the resistance of the cuticle.
4. That the quantity or rapidity of endosmose is not influenced by heat or by light.
5. That light is the only agent of the natural position of leaves, and of their turning over when inverted. The blue are the most, the red the least, active rays.
6. That light does not act in this case by a physical attraction or repulsion, properly so called.
7. That the turning over of leaves takes place sometimes by a torsion of the footstalks, sometimes by a curling of the flat part of leaves.
8. That the blue ray appears to be the most, and the red the least, active in operating the turning over of leaves.
9. That the exhalation of leaves is much increased when their inferior surface is exposed to light.
10. That the decomposition of carbonic acid and the disengagement of oxygen gas are, under the same circumstances, considerably diminished.

ON THE CAUSE OF EPILEPSY.

By JOHN JACKSON, Melton Mowbray.

In the epileptic paroxysm, especially towards its termination, there is, in addition to the insensibility and convulsions, great venous congestion of the head, face, neck, and upper extremities. Now, this congestion could not be produced, nor could it exist, if the blood could get into the heart by the superior cava. In epilepsy, then, something happens by which the ingress of blood into the heart by the superior cava is prevented. What is that something? In what way is it possible for the current which descends to the heart by the superior cava to be suddenly and temporarily arrested? The only conceivable way is by a sudden, forcible, and undue rush of blood entering the heart by the inferior auricular opening, meeting and overpowering the descending current, and so preventing its entrance by the superior auricular opening. But how could such a rush of blood through the inferior auricular opening be produced? It could only come either from the inferior cava or the cava hepatica, neither the one nor the other of which of themselves could produce it: but let us just step through the cava hepatica and hepatic capillaries, and where are we? In the hepatic afferent vessel—a vessel which consists of the venous portion of the spleen, and the splenic and portal vein and its ramifications—a vessel remarkable for its distensibility, and whose contractility must be proportionate—a vessel which receives by the gastro-intestinal or mesenteric veins the drink, digested food, and blood from the alimentary tube, and which it not only conveys to the liver but propels through it—a vessel which, although anatomists seem hardly conscious of its existence, is nevertheless the first of the three great afferent vessels, the right auricle and ventricle and the pulmonary and its branches being the second, and the left auricle and ventricle and the aorta and its ramifications the third. Now, suppose this hepatic afferent vessel were to become unduly distended, and when in that state were to contract with undue rapidity and force: what would be the effect? Would there not be a sudden, forcible, and undue rush of blood through the hepatic apillaries, cava hepatica, and inferior auricular opening, which would be very likely to flood the right cavities of the heart and prevent the ingress of blood by the superior cava? That this is what happens in epilepsy, and is the true cause of the disease, admits, I think, of the most complete proof. I shall not now, however, state all the facts on the evidence of which this theory rests. I may, however, observe that persons subject to epilepsy, when requested to place their hand on that part in which they most frequently experience pain, refer generally, if not invariably, to the region of the spleen.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of July 5; M. BRONGNIART in the Chair.

REFLEX SENSIBILITY.

In answer to the communication made at the last meeting, on this subject, by M. Magendie, M. Longet forwarded the following remarks to academy.

Numerous experiments had, since eight years, convinced M. Longet of the fallacy of the opinion brought forward by M. Magendie, and he now considers the absolute and constant insensibility of the anterior roots of the spinal nerves, and of the anterior columns of the cord, as a demonstrated and established fact.

As to the so-called "recurrent" sensibility of the facial nerve, it was incorrect to say that the branches of that nerve retained sensibility notwithstanding the section of their main branch, and lost it by the division of the temporo-auricular filament of the inferior maxillary nerve. Having on dogs removed the anastomotic

branches which unite the auricular with the facial nerve (fifth and seventh pair), M. Longet divided the three divisions of the seventh pair, and found to his surprise that with the exception of one twig, the free extremity of the distal division of the middle branch of the facial, all retained sensibility. M. Longet explained this fact by the presence of anastomotic branches thrown out by the superior and inferior divisions of the facial nerve, by which a communication is readily established with the fifth pair.

INSALUBRIOUS ARTS.

M. Morin, in a report on a new mode of ventilation applicable to the workshops of knife-grinders, made the following remarks on the insalubrity of that trade.

Amongst the numerous professions which shorten the duration of human life, that of the knife-grinder is one of the most murderous. The dangers attending the breaking of grindstones, the fragments of which are often projected by the centrifugal force to considerable distances, are not the greatest which the workmen are exposed to. These dangers have, besides, been much diminished by the improvements introduced of late years in the composition of the stones. Another cause, slow it is true in its action, but continuous and infallible, carries the greater part of knife-grinders to an untimely grave. Independently of the various anti-hygienic conditions in which they are placed, those men are frequently and periodically exposed to the inhalation of a dry, silicious dust, which escapes from the grindstones, when they are used in a state of dryness, or when their surface is altered. Laryngitis, bronchitis, and particularly consumption, are the fatal consequences of this state of things. In the sword manufactories of France, almost all the workmen die before the ages of forty or forty-five. We must also add, that the knowledge of the miserable fate which awaits them induces many to have recourse to intemperance, by which their health is still further compromised.

ACADEMY OF MEDICINE.

Meeting of July 6; M. BÉGIN in the Chair.

A letter was read from M. Orfila, in which it was stated that several members of the academy had assisted at the experiments instituted by the learned Dean of the Faculty of Medicine, for the purpose of practically demonstrating the facts laid before the academy on two former occasions, and that these experiments had been fully successful.

DEATH OF M. PARISSET.—M. Bégin announced to the academy the death of M. Parisset. Out of respect to the memory of the late "secrétaire-perpétuel," the meeting adjourned at a quarter to three P.M.

INDUCTION OF PREMATURE LABOUR. By PROFESSOR DUBOIS.—A woman, with a very deformed pelvis, was admitted into the Hôpital des Cliniques towards the middle of the month of March. She had arrived at the end of the eighth month of gestation. The patient had, on a former occasion, been delivered, with much difficulty, in the same wards, of a stillborn child. In the present instance, dilatation with the sponge tent was resorted to, and insignificant contraction was obtained. On the 17th, however, after three days' artificial dilatation, the fingers could be passed into the uterine orifice, and the membranes and head were distinctly felt. M. Dubois, in order to bring matters to a more speedy termination, had recourse to the method recommended by Dr. Hamilton, viz., the separation of the membranes from the uterus, in a circle round the mouth. In the attempts to perform this separation, with an instrument, the membranes were ruptured in such a situation as to convert the method of Dr. Hamilton into that of M. Meissner. Notwithstanding the escape of a certain amount of amniotic fluid, it was only on the morning of the 18th that labour fairly set in, and after the rupture of the membranes in the centre of the os uteri. This patient was on the same day delivered of a child, weighing five

pounds, who was at first much congested, but was soon restored. Congestion returned, however, and the next morning the infant died in convulsions. On dissection, the cerebral membranes were found much loaded with blood, and in each lateral ventricle existed a clot of the shape of a leech. Twelve months since the learned professor, under similar circumstances, induced premature labour by the exhibition of the ergot of rye; and the same congestion of the brain carried away the child, and was attributed to the ergot.

HOTEL DIEU.

ACCIDENTAL STRICTURE OF THE (ESOPHAGUS. By PROFESSOR BLANDIN.—A painter, aged thirty, pressed by intense thirst, accidentally swallowed a certain quantity of sulphuric acid, the greater part of which was instantaneously vomited. No symptoms of poisoning were, therefore, observed, and ulceration of the throat and œsophagus was the only result of the accident. After abundant suppuration, the œsophageal ulcer began to heal, but at the expense of the diameter of the tube: deglutition became difficult, and the narrowness of the stricture was daily increasing. M. Blandin applied a treatment analogous to that in use against urethral constrictions, viz., temporary dilations, to be followed by cauterization. Small catheters at first were admitted, and allowed to remain ten or fifteen minutes in the passage; each day their size was gradually increased, and at the end of three weeks, the patient was sufficiently recovered to be discharged—cauterization not having been judged necessary to complete the cure.

DEBATE OF THE ACADEMY OF MEDICINE ON THE RELATIVE MERITS OF LITHOTRITY AND LITHOTOMY.

In our last communication we were not enabled to do justice to M. Civiale's communication; it was long, important, and deserved much attention. Since the meeting of June 29, we have obtained a view of the paper, and think that, at the beginning of a debate which promises to be replete with interest, we cannot do better than to furnish at least an outline of M. Civiale's pleadings in defence of his favourite method.

After a long preamble, in which M. Civiale explained his motives for reading, instead of speaking, his communication, M. Civiale examined what was the real value of lithotripsy. In order to answer that question, it was not sufficient to bring forward detached cases, because it was impossible to say if unpublished facts were confirmative or destructive of theories established on those which were brought before the public. It would also be necessary to inquire into the precautions taken to ensure a proper diagnosis, a sufficient discrimination of cases, the necessary perfection of the operative process; conditions which should be clearly known, in order that the art might not suffer from the errors or incapacity of the artist. M. Civiale would abstain from any such research, which he considered of too delicate a nature to be undertaken without incurring the risk of giving offence. But the same reserve was not imposed upon him with regard to the results of his own practice, and the statistics of these he would lay before the academy.

From 1824 to 1826, M. Civiale had visited 506 calculous subjects, 199 of which were considered unfit for the operations of lithotripsy; 307 cases were submitted to the method:—

	aged from	7 to	20 years.
55	"	20	" 40 "
105	"	40	" 60 "
138	"	60	" 80 "

296 were completely cured; 7 died; and 3 patients were only partially relieved.

From the year 1836 to 1845, 332 calculous patients were visited by M. Civiale; 211 were operated, 91 were unfit for the new method.

Thus, out of a total 838 individuals, 548 were treated by crushing. To these should be added 25 operations, rendered necessary by a return of

the concretions; 8 combinations of lithotomy with lithotripsy; and 10 patients treated since the above statistics were drawn up, forming altogether a total of 591 cases to which, in the space of 22 years, the method had been applied; 566 cures had been obtained. In 14 instances death could be more or less immediately referred to the operation; and in 11 the cure was incomplete, the calculi having been crushed and removed, but disease of the bladder or prostate still impeding the excretion of urine.

LACERATIONS OF THE URETHRA.—At the Academy of Medicine of Belgium, on March 27, a report was read on an interesting paper by M. Didot, in which a new plan of treatment was recommended for the lacerations of the urethra. M. Didot, in three cases of violent contusion of the perineum, followed by effusion of urine, and afterwards by retention of the same fluid in the bladder, unwilling to irritate the contused and swollen parts by the presence of a catheter, made an opening into the urethra, behind the contused parts, &c., by recommending the patients to press with the finger on the anterior angle of the wound, whilst voiding urine, in order to prevent the passage of that liquid into the lacerated parts of the duct: he succeeded in keeping down inflammation. Eventually all the patients recovered, the incision of the urethra healing with remarkable speed. M. Didot proposed, therefore, the adoption of this plan of treatment in all injuries of the perineum sufficiently violent to have occasioned infiltration of urine. The advantages derivable from this method—viz., the possibility of dispensing with the presence of a permanent catheter in the inflamed urethra, the removal of a constant cause of irritation, viz., the filtering of urine between the catheter and the urethral walls—were sufficiently great to induce surgeons to look upon it with favour in those embarrassing and dangerous infiltrations which are the frequent consequence of contusions of the perineum.

DEATH OF M. PARISSET.—M. Parisset, the late "secrétaire perpétuel" of the Academy of Medicine, was born in the year 1770, at the village of Grand, in the department des Vosges. After a childhood and youth passed in the most humble circumstances, M. Parisset served in La Vendée, as a volunteer, against the Republican troops. At the close of that war he began the study of medicine, and was for many years prevented from graduating by the smallness of his means. In 1818 he was attached to the Hôpital of Bicêtre, and in 1819 sent to Cadiz to study the yellow fever. M. Parisset returned from his mission, convinced of the contagiousness of that disease—an opinion which he never departed from; in 1828 the learned academician demanded and obtained permission to study the plague in Egypt; and after a journey, which lasted no less than two years, published a small volume on "The Causes of the Plague, and the Means of Arresting the Disease," which is still considered a *chef d'œuvre* of science and style. From that period forward M. Parisset consecrated his life to literary pursuits, and his academic orations place his name near those of Thomas and Fontenelle. He was a distinguished *sevant*, an eloquent writer, and a good and kind man, whose loss will be severely felt by the Institute and the Academy of Medicine.

D. MC CARTHY, D.M.P.

Alum as an Emetic in Croup.—Dr. Meigs, of Philadelphia, prefers alum above antimony and ipecacuanha, from its certainty, speediness of action, and the little prostration it afterwards produces. It is best given in a state of fine powder, mixed with honey, syrup of any kind, or treacle. The dose is a teaspoonful of the powder, to be mixed with equal or double the quantity of the vehicle, and repeated in ten, fifteen, and twenty minutes, should the first dose fail to produce free emesis. It is seldom necessary to give a second dose. The remedy itself has no effect like that possessed in so high a degree by antimony, and to a less extent by ipecacuanha of causing adynamia of the nervous

system—an effect which in some constitutions, or when it is to be exhibited frequently, is sometimes attended with injurious and fatal consequences. Alum may be exhibited in doses above mentioned, three or four times in the course of a day for several days, without dangerous prostration or any other threatening symptoms following its exhibition.

Laceration of the Perineum.—Dr. J. P. Mettanan, of Virginia, relates, in the American "Journal of Medical Sciences," six cases of severe and extensive laceration successfully treated by operation. One of the worst cases occurred in a lady, twenty-four years of age, who was lacerated by the hurried and improper efforts of the midwife before the arrival of the physician. The injury was not discovered at the time, and six months elapsed before any attempt was made at correction. On examination, the recto-vaginal wall was found entirely divided, and the two passages bounded by it united into one, by a cleft upwards of two inches and a half in length, with its margins regularly healed over and smooth. No trace of the rectum and its sphincter muscle could be clearly identified; nor was there the least power of these organs to detain feculent matter passing into the rectum from above. From the mucous coat of the rectum, a thick massy growth of fungous development presented through the fissure into the vagina, and very slightly beyond the verge of the anus and labia externa, which was excoriated in many places. Two days before the operation, the patient was confined to a liquid diet. For the operation, the patient was placed on her back supported by a pretty high bed, with the buttock resting on, and projecting a little beyond, the bed-rail, protected by a folded blanket and sheet, and the parts exposed to a strong light. The thighs were flexed on the pelvis and the legs on the thighs, and held separate by an assistant on each side. The labia were carefully separated by inserting between them the extremities of two curved spatula, to embrace their surface completely, and making traction through them. The denudation was commenced at the verge of the vagina-rectal orifice, and continued upwards to and beyond, the angle a few lines, the separated portions being preserved unbroken. Cold water was freely injected along the line of denudation wherever blood had collected. The denuded surfaces were brought together by a sufficient number of points of the interrupted suture to approximate and maintain them in close and exact contact; and this was effected with short needles, much curved, armed with an animal-metallic ligature, inserted deeply beneath, and two or three lines beyond the margins of the denuded surfaces, with strong needle forceps constructed for the purpose. By arming the needle first with a silken ligature, doubled so as to form a noose, and connecting the bent extremity of the laden wire with it, little difficulty was experienced in the introduction of the laden sutures. They were inserted from within outwardly, and the eye end of the needle for that purpose was held by the side of the forceps, so as to leave the point of it free and salient on the opposite side of the part. After the requisite number of sutures were inserted, the wires were tightened, and their free ends twisted together, until the parts were firmly and closely in contact. Care should be taken in closing the cleft at the verge, to secure a complete coaptation to the anus. The sutures must be inserted from four to six lines apart, and in this case ten were required to close the fissure. The whole of the twisted portions of the wire were invested with oiled silk to protect the mucous lining of the vagina, and the patient was placed in bed on her left side, having her knees tied together. The bowels were suffered to repose, by withdrawing every kind of solid food. The wires were tightened on the fifth day. No action of the bowels till the seventh day. On the twelfth day the wires were cut away, when the cleft was found to be perfectly united. The bladder was evacuated for the first week by a gum elastic tube.

Anteversion of the Womb with Adhesion of the Os Uteri to the Body of the Fourth Lumbar Vertebra.—The patient was a married woman, who had been afflicted for a considerable length of time with what was supposed to be, by her friends, cancer. Dr. Samuel Tyler, of Fredricksburgh, United States, saw her about four months before her death, when he found her with a feeble pulse, pale and anxious countenance; a discharge of pus and sanguineous fluid of considerable quantity from the uterus, without much pain. An examination revealed an orifice the size of the os tinæ, not much dilated, discharging the fluids above mentioned. Her condition continued without improvement till the period of her death. Upon a post-mortem examination the uterus was found to be healthy, but perfectly antverted; and the os uteri closely adherent to the fourth lumbar vertebra. On making a transverse section of the womb, there was found within its cavity a full-term fetus, and the opening which was discovered, per tunicam, in life, was now found to be a fistulous orifice, made through the under portion of the cervix, by the pressure of one foot of the fetus, the bones of which had discharged themselves, per vaginam, unobserved; the fetus being perfect with the exception of the bones of the left foot. This case is singular, and the position of anteversion is one not noticed by many of the best authorities.

Singular Case of Laceration of the Broad Ligaments.—The patient was a married woman, and attended by Dr. G. T. Allen, of Marine, Madison County, U.S. While arranging a window curtain she fell a distance of about four feet across the top of a chair. The immediate effects of the fall were a slight gush of blood from the vagina, and an inclination to faint, which continued for several hours; after its subsidence, she seemed as well as usual, with the exception of pain in the soft parts that had been bruised; these were so much hurt as to prevent any other than a superficial examination, and to induce a full belief that the only injury was external. For two days there was no other unpleasant feeling than that from the outward injury. On the evening of the third day she was seized with syncope, which lasted for several hours. These fainting fits returned at intervals for the space of a year, when they ceased. At times she suffered from numbness of the left leg, prolapsus uteri, nervous irritability of the womb, hepatic torpidity, and disturbed sleep. A moderate leucorrhœal discharge was ever present, and prominent symptoms of typhilitis uteri troubled the patient from October, 1844, until she became *puerpera*, in September, 1845, and returned after parturition in June, 1846. During the period of uterogestation she suffered less than before its commencement. She seemed as well after confinement as before gestation, until August 23, when a slight dysentery commenced, with a feeling of distention and violent agony in her stomach; and on the 29th she died. At the post-mortem examination, the broad ligaments were found to be ruptured, from the fundus to the cervix uteri; the womb lay upon the sacrum, and evidently rolled from side to side of the pelvis, as the patient turned in bed. The vessels in the lacerated part of the broad ligaments resembled a black vermicular mass. The neck of the bladder, with every part within the pelvis, was much tumefied, and there was considerable engorgement of all the pelvic bloodvessels. The lumbar vertebrae were ulcerated, and abraded to the amount of nearly one half their transverse diameter, and the remaining part had lost its firmness. The posterior part of the intervertebral ligaments seemed too thin, and the longitudinal measurement of the lumbar vertebrae, posteriorly, was much diminished by absorption; hence there was inability to bend the spine backwards in life. The spinal marrow was perfectly sound.

On the Cause of Yellow Fever.—The theory of Dr. John Harrison, professor of physiology and pathology in the Medical College of Louisiana, maintains of the etiology of yellow fever is, that from the accumulation of filth in large cities (chiefly nightsoil, and the animal

matter of urine), putrefaction must necessarily take place, and upon this putrefaction, under certain meteorological conditions, there is generated a poison which, either in the form of a volatile oil or other organic matter, held in solution by ammonia, floats in the atmosphere, is inhaled during the respiratory movements, is taken into the circulation, and poisons the system. It produces specific effects, as much as the matter of smallpox or scarlatina. The formation of this poison begins under certain meteorological conditions which are utterly unknown to us, continues while they last, and ceases with them. As we have said before, the poison is not a gas, but a volatile substance constituted of organic matter—as much so constituted as the matter of smallpox or hydrophobia. In his opinion, yellow fever does not depend on putrefaction alone, nor on meteorological influences alone, but on both conjoined; when this conjunction occurs, seething laboratories of poison are put in operation at different parts of the city.

Fish-bone in the Trachea upwards of Two Years.—Dr. W. B. Herrick, of Rush Medical College, relates the case of a young man, twenty-five years of age, who was suddenly attacked with cough, profuse expectoration, and difficult respiration, with slight febrile excitement. For two years after this attack, these symptoms became more and more alarming; his sufferings were almost insupportable; and at the end of that time, these apparently characteristic symptoms, his emaciated condition, and depressed physical powers, impressed the conviction on himself and others that he was consumptive. Some time afterwards, during one of the violent fits of coughing to which he was subject, a foreign substance, which proved to be a fish-bone, cuboidal in shape, and half an inch or more in diameter, was suddenly and forcibly ejected from the laryngeal opening, upon the floor. From this time all the alarming symptoms began rapidly to abate, and he was eventually restored to perfect health. The patient recollected afterwards that a month or two previous to the appearance of the above-named symptoms, while dining upon fish, he inhaled, as he supposed, a small portion into the air-passages; but, as it gave him little trouble at the time, he thought no more of it, and did not during his illness suspect even the true cause of his sufferings.

Ischuria Renalis.—Dr. R. E. Little, of Quincy, Florida, reports a case of this disease occurring in a mulatto girl, eighteen years of age, which is remarkable for recovery having taken place after a total suppression of the urinary secretion for ten days. During the whole of this time the sensorium of the patient was affected; at one time she was delirious, and at another comatose. Her complaint seems to have been a form of hysteria.

Strychnine in Cholera.—Dr. B. R. Hogan relates two cases of cholera successfully treated by strychnine in doses of one-twentieth of a grain three times a day. He says, also, that he has used strychnine with much advantage, as a tonic, in the convalescence from intermittent and congestive fevers. No relapse of the latter has followed its use. In *subaditus tendinum* from extreme exhaustion, in an anemic patient with diarrhoea, it has formed a most valuable combination with the *peresqui nitratu ferri*. In the atonic dyspepsia of the habitual drinker who wishes to reform, it has a comforting and permanent value.

Imperforate Prepuce.—Dr. J. C. Cain met with a case in an infant which was not discovered till the next day after its birth. On examining the part, it was discovered that the prepuce had no orifice, but merely a fold of the skin simulating one. The operation of circumcision was performed without delay; and a probe passed into the urethra as far as its membranous portion, to ascertain that there was no obstruction in that part of the canal. Forty-two hours elapsed from the birth of the child until the excretion of urine took place. What is remarkable is the circumstance of there not having been, to all appearance, any exit of urine from the bladder into the

sack of the prepuce. The probability is, that there was no secretion for several hours after birth, as no prominence of the bladder was perceptible, and the child was not fictitious.

Absence of One Kidney. Dr. Geo. N. Burwell, of Buffalo, in examining a patient who died of diabetes and anasarca, found the kidney and ureter of the left side entirely wanting; no trace of them was to be found in any part of the abdomen.

Prolapsed Cord not Pulsating, yet Child B Alive.—Professor Gillman, New York, attended a lady in labour with her third child. The shoulder presented by its anterior surface, the clavicle occupying the centre of the os uteri. A large fold of cord protruded from the vagina, and hung pulseless between the thighs. The soft parts were well dilated, and the uterine action not excessive. The child was turned, and delivered by the feet without delay. It was asphyxiated, but by friction with hot flannels, and an occasional dash of cold water upon the chest respiration was excited in less than half an hour.

A Child Born at the Ninth Month of Uterogestation, passing through an oblong Aperture under one inch in its narrow, and two inches and a half in its long, diameter.—The case is related by Dr Simpson, of Edinburgh, in "The Monthly Journal of Medical Science." The patient was a woman, thirty-four years of age, originally well formed but, from the effects of malacosteon, the bones of the trunk and extremities became shortened and deformed; and, from being a somewhat tall woman, sunk down in the course of seven or eight years into a deformed dwarf-like figure, measuring about four feet in height. When first seen after her pregnancy, it was so far advanced as to preclude the idea of delivery by the induction of abortion or premature labour, and all attempts to touch the os uteri, on account of the deformity, were ineffectual. After the labour commenced, when the medical attendant, Mr. Wiseman, arrived, he found the soft scalp of the child already bulging through the external parts. Some detached bones, included in the portion of scalp that had passed, allowed him to obtain a firm hold of the protruded portion of the head, and thus enabled him to use some extractive force. In half an hour, by this assistance, the child was entirely born. The time at which the child died cannot be accurately determined, as the mother imagined she felt it living and moving up to the time of her delivery. She has made a good recovery. The infant measured 18½ inches from the crown of the head to the heels; but its limbs and body were thin, lank, and atrophied; and its weight was only three pounds two ounces. The placenta was small and atrophic, and contained, scattered throughout it, a number of those white tubercles which we so often see connected with and causing marasmus and death of the fetus *in utero*. Some of these tubercles were of the size of hazelnuts. The pelvis of the mother was excessively deformed and contracted. In front the walls felt, on examination, doubled or collapsed together; and the outlet, which was the only part that could be very accurately examined, was exceedingly deformed and diminished in size. It was impossible to introduce two fingers between the tuberosities of the ischia; hence this diameter of the outlet was evidently under an inch. Posteriorly, or opposite the sacro-sciatic ligaments, there was transversely more space; but the strong anterior curvature of the coccyx and lower end of the sacrum seemed to curtail the conjugate diameter of the opening, and to prevent the possibility of admitting, when fully dilated, more than three or, at most, four fingers, even in this direction.

On the Prevention of Infection from Wounds in Dissection.—Professor Hargrave, of Dublin, recommends the following plan to be adopted when either of the fingers or thumbs are wounded:—Wash them well for a few minutes in cold water, and then suck them; immediately after apply a ligature above the cardiac side of the wound, with such tightness as will induce decided congestion, which will be indicated by the

colour of the parts; some blood will also flow from the injured surface, and a certain degree of numbness will follow the application. The ligature is then to be firmly tied and knotted, and allowed to remain on for at least twelve hours; it may be kept on for double that period. Before commencing *post mortem* investigations it is well to smear or rub into the hands any bland oil: this supplies an additional coating to the epidermal one, and will act as a means of closing any very minute and superficial abrasion which might exist, though the individual is not aware of it.

A New Way of Operating for Ectropion.—M. Blasberg is inclined to think that the proximate cause of this disease consists in a prevailing contractile power in those fibres of the orbicularis which surround those that form the ciliary portion of the muscles. In a man fifty years of age, with sarcomatous ectropion, a furrow below the ciliary margin of the lower lid was found, which became deeper every time the patient closed his eye forcibly. A vertical incision was made in the lid, and some of the fibres of the orbicularis being much contracted they were divided, and the ectropion was cured. In another case a horizontal incision was made, about three-quarters of an inch long, and, the orbicularis being exposed, some of its fibres, which were most contracted, were divided at three different places, and which were situated at about a line below the ciliary margin. In a short time the disease disappeared.

Sulphate of Quinine in Aneurism of the Aorta.—It appears that sulphate of quinine has been employed with much success in some of the Italian hospitals for the relief of aneurism of the aorta, and other internal aneurisms. It has, says its supporters, the immense advantage of bringing down the pulse, without disturbing its rhythm; of making the badly coot of the blood disappear; that is, of dissipating the organic condition, arteritis, on which it depends, and thus, of retarding the progress of the aneurismal tumour. The other hyposthenies adapted to the same end, according to the same authorities, as by alternation with the sulphate of quinine, are the vegetable and mineral acids, the sulphate of iron, the ergot of rye, the cold ferruginous waters, the arsenious acid, the acetate of lead, and the iodide of potassium.

Monstrous Birth.—M. Huron was called to a patient in labour for the sixth time. On making a vaginal examination, he found that the fetus presented its pelvic extremity, and presently four feet protruded from the vagina; afterwards the thighs and the lower parts of the trunk were disengaged; and lastly, one umbilical cord inserted below the point of junction of the fetus; the uterine contractions continued until the lower part of the common thorax was extended, and then there remained no doubt of the nature of the monstrosity. After the lower part of the chest was born, the delivery did not advance in the slightest degree. The hand could only be introduced a short way into the pelvis, towards the sacrum, then it met with bulky resisting mass, formed by the two necks and heads. The fetus showed by their movements that they were alive when the legs were protruded, but they were now dead, in consequence of pressure on the cord. Traction upon the four limbs was first tried without any result; an attempt was then made to push back one of the fetuses and extract the other, to tilt the one over the other, so as to cause their successive and not simultaneous entry into the pelvic cavity: this plan, also, was found unavailing. Forceps could not be applied, and it was resolved to cut away one of the bodies as far as possible; and as it was obvious that the head next the sacrum could be more easily drawn down, than the head next the anterior wall of the pelvis—for the latter would probably hitch upon the symphysis pubis—the anterior fetus was for this reason cut away, and a bistoury was passed through its body, between the eighth and ninth dorsal vertebra. This body being removed, the operator was enabled to exert traction upon the posterior fetus, much

more in the direction of the pelvis, and by this measure the posterior head, closely followed by the other, gradually passed through the pelvis.

Mercury in the Pus of a Bubo.—A man was ordered to rub in several ounces of mercurial ointment, in order to disperse a bubo. After poulticing, the gland was opened, and, upon analyzing the pus, unequivocal traces of quicksilver were found.

REVIEWS.

The Physiological Anatomy and Physiology of Man. By R. B. Todd, M.D., F.R.S., &c., and Wm. Bowman, F.R.S., &c. Part III. Pp. 200. London: John W. Parker. 1847.

Anatomy and Physiology are two most important branches of medical education, as they lead to a correct knowledge of the structure and functions of the various organs of the body, without which these aberrations which constitute disease cannot be rightly understood or properly treated. The physician, therefore, whose aim is to practise his profession with the greatest credit to himself and advantage to others, will cultivate with persevering application those departments of science which modern chemistry and the use of the microscope have rendered increasingly interesting and important. The work by Dr. Todd and Mr. Bowman, when complete (if we may judge from the parts which have already appeared), will prove a valuable addition to the medical library, and will be an honourable testimonial of their own industry and intelligence.

The third part, which has recently issued from the press, treats of the organs of smell, vision, and hearing; of the encephalic nerves, and sympathetic; and of digestion. In order that our readers may form a correct judgment of the work, so far as it has been published, we give a single extract, taken from the present number:

"The mucous membrane of the stomach demands, and will repay, an attentive study. It is of that variety which has been termed *compound mucous membrane*, i.e., its thickness is made up of an infinite multitude of tubular involutions of the simple membrane, with intermediate vascular and other tissues, sent up into it from below. The simple membrane consists of basement membrane, and epithelium, both of which are found throughout. The vessels are uniformly on the deep surface of the basement membrane, and the epithelium on its opposite surface. The compound mucous membrane of the stomach is thinnest near the oesophagus, and is usually of a pink colour in the middle region, and paler towards the pylorus. Over the whole surface of the membrane, as seen on laying open the organ, and stretching it so as to obliterate the larger folds, there are visible, even with the naked eye, but still better with a lens, a multitude of cavities of very irregular shape, and about 1-200th of an inch in diameter, more or less. These cells are not the result of creasings of the membrane, and they do not disappear when it is stretched. They are usually filled with mucus, which requires to be removed. Over the greater part of the stomach they extend in depth about one-eighth or one-sixth of the thickness of the membrane, but they are larger and deeper near the pylorus. In the ridges between them runs a plexus of vessels larger than ordinary capillaries, and which often retain its blood after death, so as to map out the cells in a beautiful manner. This plexus is supplied by vessels sent up from below, and may be very easily injected artificially. The epithelium which lines these stomach cells, and covers the ridges between them, is of the columnar variety; the particles are shorter than in some other parts: one end is free, while the other is directed towards the basement membrane; and they contain each a clear pellucid nucleus near their deeper end. They seem to lie in a double series, the deeper being in course of development, while the more superficial is in course of decay. It has appeared to us that each particle, when arrived at maturity, has, besides the nucleus, granular

contents enclosed; and that, at a subsequent period, the granular contents escape at the free extremity by a dehiscence or opening of the wall at that part, leaving the transparent husk with its nucleus subsisting for some time longer. The clear structureless mucus, which is almost always found occupying the cells and covering the surface of the membrane, seems to be the altered contents of these particles after their escape, for the uniform existence of a minute cavity in the centre of it, where it fills the cells, shows that it has dozed out from every part of their wall, so as gradually to fill them up. It has been said that the cells are so shallow as to dip into the compound membrane only about one-eighth of its thickness. The rest of its thickness, except near the pylorus, is made up of minute tubular offsets from the bottom of the cells, which may be termed the stomach-tubes, and which pass vertically, two, three, or four, from each cell, afterwards subdividing again and again, and becoming more or less tortuous, till they terminate by blind extremities on a dense tough layer of areolar tissue continuous with that laxer stratum which separates the mucus from the muscular coat. The stomach-tubes have a basement membrane, and contain an epithelium altogether different from that which has been just described. Its particles are of the glandular variety, are rounded in shape, without obvious walls; their contents are darkly granular, often mixed with oil globules, and their nucleus is less distinct. The tubes are so narrow that the particles seem to fill them, and obliterate their cavity, except near their orifices, where they empty themselves into the cells. Towards their blind extremities they often seem to be simply a series or pile of epithelial particles; and this has led some anatomists to deny that they are tubes. The existence, however, of a basement membrane convinces us that they are to be regarded truly as tubes, permanently laid down in the tissue of the stomach, for the origination and discharge of the materials of their peculiar epithelial particles on its inner surface. The tubes proceed in sets, corresponding to the cells into which they open; those of each set being enclosed in a common envelope of nucleated tissue like the matrix of the kidney and some other glands. This firm investing structure is attached, on the one hand, to the dense layer on which the compound membrane rests, and on the other to the ridges between the cells; and it sends delicate processes between the individual tubules of each set, and between their branchings, so as to sustain every portion in its proper place. Between the sets of tubules the large vessels run up to the ridges between the cells, and every tubule is invested with capillaries, which take for the most part an upward direction, and are cut across with the tubules in a transverse section of the latter. We have met with no tubular-nerve fibres in the mucous membrane of the stomach; but it is highly probable that nucleated-nerve fibres run among the tubes, though their want of characteristic features renders it difficult to positively assert their presence."

The descriptions are lucid, and the woodcuts with which the parts abound are well finished.

De Saliva. Indagationes Physiologicae, &c. &c.
A. CAROLO STRAHL, M.D. SVO. Berolini:
Typis Gustavi Schade. 1847.

This is a Latin translation of the physiological and chemical part of the learned treatise on Saliva by Dr. Wright, of Birmingham, other translations of which have already been reviewed in our pages. The original work, as our readers are aware, appeared in the columns of a contemporary, before Dr. Wright became one of the regular contributors to the *Medical Times*. As the treatise first came out, it was regularly translated into the periodicals of France, Italy, and Germany; subsequently, it has been reprinted in America; translated into German as a separate work, and amply annotated by Dr. Eckstein, of Vienna; into Dutch, and annotated

by Dr. Rienderhoff, of Amersfoort; and into Latin, by Dr. Strahl, of Berlin. The last is the translation which lies before us. It is well done, and reflects excellent credit upon its author, who in all leading points has well preserved the features of the original—not always an easy task in converting scientific English into Latin, considering the late advances in the use of technicals and particular modes of expression. As regards the original production, perhaps the best praise we can give it is to repeat the fact of its reprint in America, and its translation into five continental languages, within three years of its first issuing in this country. It is one of those rare works of combined industry and genius of which English medical science, and ourselves as one of its exponents, have a just title to be proud.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Book-seller, or it will be sent direct by post from the Office of the *Medical Times* to Subscribers sending by a Post-office order, directed James Angerstein Curfrace, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

Delta.—It is necessary that two qualified medical practitioners should sign the certificate. A Licentiate of the Apothecaries' Company may do so.

Mr. Benthum.—The arrangement should not be delayed by any speculations about a Medical Bill.

One Afloat.—We are much obliged to our correspondent for his information, which, however, it would be imprudent to publish at the present time. The matter is under the consideration of high official personages.

Medicus.—The abnormal condition is produced by deficient action of the skin, the peculiar nature of the ingesta, and derangement of primary assimilation.

J. B., Torquay.—The prescription is evidently not the production of a scientific practitioner. It is a mere jumble of ingredients, without any regard to chemical reactions. We do not prescribe through the medium of our columns; and we would recommend our correspondent to consult immediately some respectable medical gentleman.

Candidus, Queen-street, City.—Our correspondent should remember that the discussion was one of considerable interest to many medical practitioners. It is to be regretted that differences of opinion seldom fail to become matters of personal recrimination.

J. C. Holland.—Experiments have been performed to show the identity of smallpox with cowpox. Our correspondent's paper is under consideration.

Students.—The case of abscess of the heart has been received, but cannot be inserted without the reporter's name.

A Practitioner with Two Qualifications.—Much perseverance is required to overcome the habit complained of, but we think a careful and slow mode of speaking will be one of the best means of removing the imperfection.

A Constant Reader.—1. Dr. Rigby's System of Midwifery will, we think, suit our correspondent's views. 2. Gregory and Celcius are the two Latin authors used at Apothecaries' Hall to test a student's knowledge of the language. 3. Hippocrates was born in the Island of Cos, one of the Cyclades, in the 80th Olympiad. He wrote his Aphorisms in the Ionic dialect.

The article on Medical Galvanism cannot be inserted except as an advertisement.

A Medical Apprentice.—The indentures are binding, and, without the gentleman's consent to whom our correspondent is articled, he will be obliged to remain the full period.

A Scotch Graduate.—We cannot offer an opinion on the case; the operation, though sanctioned by the practice of Lisfranc and other eminent sur-

ons, is not resorted to except under very urgent circumstances.

A Licentiate and Subscriber.—The party is identically liable, under the Apothecaries' Act. Whether the Company, under all the circumstances, could stir in the matter is rather doubtful.

Mr. Edward Benthall.—We are sorry we cannot oblige our correspondent by giving him the information required. We are not aware of any published statistics to which reference may be made.

A Non-Medical Reader.—The establishment under which Dr. Costello presides is one in which he unfortunate patient will meet with all the skill and attention which his case requires.

Vindex.—A coroner has the power of summoning my qualified practitioner; it is right, however, that the gentleman who is called in to the case should be the one summoned.

A Practising Apothecary.—There is no remedy for the evil. Druggists too frequently play the part of medical practitioners.

Medico-Chirurgus.—There is no law to prevent a licentiate of the Hall practising any branch of the profession; nor is there any law that compels a medical practitioner to take out the diploma of the College of Surgeons, if he engages in performing surgical duties.

G. G., Oxford.—The fee for the diploma of M.D. of the University of Glasgow is, we believe, about twenty-six guineas.

A Correspondent, who dates his letter from a hydropathic establishment near Regent's-park, addresses a long letter to us on the treatment of tetanus, by a Mr. Rayer. Our correspondent says that "the usually-styled nufferish method is the best, and most sure of all kinds of tetanus." He recommends, the day before the treatment commences, that the patient should have about half his usual quantity of food. "The next morning, about five or six o'clock, the patient has to commence taking the following medicines, prepared on the previous day, and arranged in four numbers, 1, 2, 3, 4. Nota bene: The patient must be up and walk in the room whilst he takes the medicines. First, No. 1, consisting of three or four trachms of pulvis radius filius maris, which he must swallow with some water that has been standing in the room. After half an hour he takes No. 2, which is the same as the first powder. After another half hour he must take No. 3, a bolus, consisting of pulvis hellebori virgii scammoniu, and gumi guttæ, of each about ten or fifteen grains; and in a quarter of an hour afterwards, No. 4, which is another similar bolus. As soon as the patient feels the worm coming, which is usually about an hour after the purgative, an attendant must assist in slightly drawing the worm, as it is always inclined to retrograde. After the operation I prescribe for him olei empyreumati (pyrolignosi), a spoonful to be taken every three hours in water, which will destroy the rest of the worm!!!"

A Subscriber, Ireland.—We think so.

Letters and communications have also been received from Mr. Edward Benthall; A Non-Medical Reader; Vindex; A Practising Apothecary; Medico-Chirurgus; G. G., Oxford; A Subscriber, Ireland; A Licentiate and Subscriber; A Scotch Graduate; A Medical Apprentice; A Constant Reader; Students; A Practitioner with Two Qualifications; J. C. Holland; Candidus, Queen-street, City; J. B., Torquay; Medicus; One Afloat; Mr. Benthall; Delta; Dr. A. Wynn Williams, Bangor-street, Carnarvon; Mr. John Alex. Morris; An M.D., of St. Andrew's; E. J. M., Drury-lane; Mr. A. W. Duke, Mullingar; Wundarzt, Glasgow; and Mr. Moriarty, Dieppe.

Wundarzt, Glasgow.—We must refer our correspondent to the Editor of the *Pharmaceutical Times*. We shall be obliged for the communications promised.

Mr. A. W. Duke, Mullingar.—The letter is handed over to the Editor of the *Pharmaceutical Times*.

E. J. M., Drury-lane.—A respectable medical practitioner will, upon being consulted, afford relief.

An M.D., of St. Andrew's.—The letter has been received.

Mr. Morris.—Our correspondent will see that his paper has not been overlooked.

THE MEDICAL TIMES.

SATURDAY, JULY 17, 1847.

THE MEDICAL PROFESSION AND THE FUTURE—ITS POWER OVER MORALS.

Few, perhaps, will dispute the truth of the proposition, that happiness is the great end of existence, and that all earnestly desire this inestimable blessing. It matters not in what rank an individual is placed, or what the action he performs: he is animated by one desire, which is alike felt by prince and beggar. Civilization, rightly directed, is society under the progress of refinement—the knowledge of mind practically applied to the production of general happiness. Like everything, however, which emanates from beings of limited knowledge and corrupt bias, it is liable to such obstructions and perversions as often produce the ruin of the most powerful empires. We, who now live in these later periods of the world's history, are permitted to search the archives of ancient kingdoms, where we can discover that truths, practically operating on the morals of society, irresistibly produced national greatness, while, in proportion as their influence was counterbalanced by riches and luxury, the splendour of greatness declined till it sunk in the darkness of an endless night. To the wealth of Greece and Rome must be attributed the sad catastrophe of their irretrievable ruin, for, in proportion as the means of senseless gratification were acquired, so were they employed to the utter subversion of morality and character. Wealth has always been, with but few exceptions, the powerful antagonist of human excellence, not that this is of necessity the case, but from the means which it affords of indulging indolence, gratifying passion, and developing pride.

In women of fashion we have a striking development of the evils resulting from ample means, used without those motives which stimulate to an activity productive of good to others, and of true enjoyment by themselves. The ethics of the school in which they have been instructed is a vain philosophy, which has taught them to consider happiness as only to be found in the excitement of the theatre, the ball-room, or at the concert. Scarcely is there any delusion by which they can be greater sufferers in their own physical happiness, while they are unfitted for active benevolent exertion for others. The victims of an over-excited and ill-regulated nervous organism, their very anticipations curtail their enjoyments, and, when the wished-for pleasure arrives, often does it produce a secret melancholy, because it does not bring with it all that was hoped; hence they become by degrees fastidious in the choice of pleasures, languid in the enjoyment, yet miserable under the want of them. The truth is, there is a limit at which these pleasures soon arrive, and from which they ever afterwards decline. They are by necessity of short duration, as the organs cannot continue their emotions beyond a certain length of time; and, if the endeavour is made to compensate for this imperfection in their nature by the frequency with which they are repeated, then more is suffered than gained by the fatigue of the faculties, and the diminution of sensibility.

It is true—as we are aware—that we have in this article been led, in following out our reflections, to deflect from those physiological conditions (our more especial department) which are to receive our attention in the succeeding number; but we have thought it not undesirable to glance, in the first place, at that moral aspect of the question which, to well-regulated minds, must attach much importance to the subsequent demonstrations of medicine.

This fashionable dissipation not only requires correction, because of the injuries it inflicts upon the votaries themselves, but also on account of the evils it entails on the social relations. Every woman, whatever her station, has in general to discharge the duties of wife, mother, and citizen. As a wife, the slave of fashion must leave the management of her household to others; and there cannot be the exercise of those affections and of that authority which are essential to constitute a well-regulated family. In the relations of mother, the evils are still more apparent. To her is committed especially the early discipline of the youthful mind, and the education of the infant has a most important bearing upon the future conduct of the adult. If any great moral change is to be effected in society, it must be brought about through the influence of maternal discipline. The ambition of the Spartan mother was to educate her child so that he might become a good citizen and a valiant soldier; and, so long as this was kept in view, Lacedæmon stood unrivalled amongst the nations of antiquity for virtue and courage. The emancipator of the great modern trans-Atlantic republic received his first impressions of piety and patriotism from his mother's lips; and the hero of the "Iliad" would never have been renowned in epic verse if his mother had not by her efforts prepared him for his greatness. It is a well-ascertained fact that early impressions influence the character and the life beyond all others, and remain strong and vivid after most others are worn away.

But what must we expect of those who, from the very first, commit to others the sustentation and care of their children, and who view the onerous duties of the maternal relationship as so many barriers to the full enjoyment of pleasure? Shall we expect that such will inspire their children with a contempt for the vanities of fashionable society; that waste of the golden hours of life; that sickly devotion to amusement; that pitiable dependence on trifling to help them along through their present tedious existence? Few are entitled more to sympathy, as certainly few are more to be blamed, than those who teach their children to find their enjoyment only in diversions, and to consider a dance, a visit, a play, or a novel, as the only thing that can keep them from sinking into gloom and despondence. The children of aristocratic parents are early taught to believe that they are destined not to usefulness, but enjoyment; and that, therefore, they are privileged to be idle.

But what can be said of these high-born females as citizens, except to their disadvantage? Without the exhibition of prudence, fortitude, temperance, and benevolence, their existence confers no lofty boon upon society, and can be no other than a burden to themselves.

The redemption of these slaves from the hands of a taskmaster, more cruel than the Egyptian Pharaoh, is mainly to be accomplished through the instrumentality of the profession. It is an undertaking fraught with charity and pregnant with blessings to our country—one

which will restore to honour, to usefulness, and to happiness, a class of individuals interesting on account of their sex, as well as their position in society, and whose influence, operating benignly on succeeding generations, shall make them truly renowned.

How can we have fresh impulses, healthy thought, or useful action, when existence is divided between enervating languor or wasting excitation? The nerves, forced in turns into excessive action or apathy, and the whole of that muscular system which nature formed for so much action, left unemployed—unused—exercised. Foul air—all but useless exercise—incessant stimuli, successively through the differing senses—irregular and partial action of the organism—how can these fail to produce, with those physical evils of hysteria, hypochondria, &c., a perfect incapacity for the higher duties of social and moral existence?

THE APOTHECARIES' COMPANY AND THEIR LICENTIATES.

WHEN a medical corporation is in possession of power which may be very useful to the profession, it is but right that that power should be carefully and legitimately employed. In the present agitated condition of the medical commonwealth, the abuse of authority or the neglect of duty in chartered institutions is not only quickly discovered, but keenly resented. It is no time, therefore, for men in office to slumber at their posts, when the commonalty are deeply sensible of their wrongs, and are struggling to free themselves from yokes which have galled them so intensely as to become too grievous to be borne.

The cupidity and tyranny of the College of Surgeons have been exposed and denounced, and that guilty corporation has been branded with a mark of ignominy which a long succession of virtuous efforts will alone be able to efface. The sale of its diploma has been a fraud upon the profession, for the council of the College has endeavoured to make it a source of profit to themselves, and of keeping as low as possible the education of general practitioners. It has been admitted that the Apothecaries' Company has counteracted to a considerable extent the great injury which threatened the profession, and that, by the power which law has conferred on this corporation, the College has been compelled to adopt a respectable curriculum of education, however lax it may make its examinations. The Company, however, stands charged with a dereliction of duty, for having disregarded the repeated entreaties of some of its licentiates to prosecute certain individuals who are illegally engaged in medical practice. We published some time ago a communication from a gentleman, near Nottingham, in which he complains of having addressed, within the last twelve months, nearly a dozen letters to the society, relative to the prosecution of a person practising without a qualification, who has not had the slightest notice of their receipt. It appears that this gentleman collected evidence which, according to his statement, would indubitably lead to conviction; and he engaged to prosecute at his own expense, if the society would furnish him with such instructions, derived from their past experience, as would put him in a train most conducive to a favourable result. If such was the case, it was to be expected that the society would at once have complied with the request. The act of 1815 is an important trust; and the body of licentiates brought into existence

by its operation has a right to expect that protection which the law affords. The prosecution of offenders is not like it once was—an uncertain and expensive business; but is now an easy, safe, and cheap way of ridding the profession of unqualified practitioners. In two instances has the new interpretation of the penal clause been put to the test, and not a shadow of a doubt now remains that offences against the act can be punished as a misdemeanour.

This penal clause, however, must at the present time be a source of very great uneasiness to its possessors, though it is fraught with advantages to them. It is beginning to be suspected that all the Company cares about this part of their law is, that it is a source of considerable profit, frightening, as it does, many into an application for the certificate. These candidates imagine that, when they have been introduced into the professional fold, the penal clause, acting like an impregnable barrier, will keep out all who are forbidden to pasture in the sacred enclosure, such as quacks, drug-sellers, and impostors. The poor licentiates, however, soon find that they may be worried with impunity by any one who chooses to do it. The law is used for no such purpose as their protection, and, if they cannot fight their own battles, the corporation, thinks it, perhaps, a very hard thing for it to be expected to stand forth as a champion. But who is to defend the licentiates if those who granted them their license will not? or of what good is, it without the strong arm of the law entwining about it for dignity and safeguard? The profession has praised the Company for its efforts on behalf of medical education, but the certificate has been secretly despised, because its plebeian origin gives it little consequence in the eyes of the public. The result is that numbers, having obtained the diploma of the College of Surgeons, engage in general practice, leaving the Company the nice alternative of prosecuting them for an infringement of the law, or of displeasing the licentiates, who consider that the restraining of such from general practice is but an act of justice to themselves. It is evident that the present order of things cannot continue long; and there are indications that the days of the Company as a licensing body are numbered. Its house must be set in order; and, in the last will and testament of the corporation, let it take care that the licentiates are not left in a less honourable position than that which they now occupy.

GENERAL MEDICAL ANNUITY FUND.

[To the Editor of the Medical Times.]

SIR,—I enclose for insertion in your valuable journal the following abstract of the proceedings of this society. It is highly gratifying to Mr. Daniell, and I am sure it must be equally satisfactory to the profession generally, to find the determined zeal which is evinced by the supporters of this fund, to carry it out in its simple integrity as a measure calculated to meet those contingencies which, although common to every class of profession or business, are peculiarly so to the medical practitioner. There can be no doubt that a very few years of active co-operation will place this fund in the position of an enrolled society; and, as its operations will extend throughout the whole of Great Britain, it may become a great national institution, calculated at once to meet those acknowledged wants felt so extensively by the widows and orphans of medical men. As already upwards of forty gentlemen have voluntarily promised active co-operation as honorary local secretaries, I hope I may be pardoned in urging this part of our plan

peculiarly upon the profession, and, if there be any gentlemen still willing to join in these duties, that they will honour me with a communication; and I assure them it will be my pleasure as well as my duty to furnish them with every information they may require.

I have the honour to remain, Sir,
Your obedient servant,
JOSEPH STAINES.
Savings Bank, Newport Pagnell, July 10.

At a meeting of the acting committee of this fund, held on Tuesday, the 6th of July, at Edward Daniell's, Esq., Newport Pagnell—present, John Rogers, Esq., Newport Pagnell in the chair; Edward Daniell, Esq., Newport Pagnell; Dr. Barker, Bedford; G. Harvey Betts, Esq., Watford; H. L. Smith, Esq., Southam; Dr. Pritchard, Northampton; Thomas Parker, Esq., Woburn; George Kelson, Esq., Sevenoaks—

The Chairman having read the resolutions passed at the general meeting at Northampton, on the 1st of June last, appointing the committee, The Secretary laid before the meeting a list of the members of the Institution, with the amount of their donations and subscriptions to the 30th of June last, being the close of the second year, together with a general statement of the funds up to that time; when the same, having been examined, was approved and ordered to be entered upon the minutes.

Resolved—"That the Treasurer be requested to invest £200 in the names of the trustees of this society."

The Secretary also laid before the meeting a draught of the amended rules and regulations for the management of the society; and, the same having been deliberately considered and discussed, it was resolved "That the rules and regulations, as now signed by the chairman, be the rules and regulations of this society, and that 500 copies of the same be printed for distribution amongst the subscribers and friends of this institution."

The Secretary laid before the meeting a draught of a prospectus of the society. Ordered that 1500 copies of the same be printed for general circulation.

The Secretary also laid before the meeting a list of gentlemen who had offered their services as honorary local secretaries. Resolved—"That the offer of the services of these gentlemen be most gratefully accepted, and that the secretary do write to each gentleman a letter explanatory of their duties, and forward to them the prospectuses and rules of the society."

REMARKS ON THE POTATO DISEASE.

[To the Editor of the Medical Times.]

SIR,—A most important article in the dietary of nearly the entire human family is on the eve of a momentous crisis—of preservation, or of annihilation; any observations, therefore, which can shed the smallest light over the late malady with which it has pleased Providence to afflict it, and with which we look upon it as now threatened, must be regarded with considerable interest by all—by the illiterate as by the scientific. Many learned articles have already appeared on this anomalous subject, with greater or lesser claims to attention, but all with the same philanthropic view and, I regret to have to add, poverty of result. Neither philosophy nor agriculture has derived much, if any, benefit from their investigations, theories, or promulgations. The cause of the potato disease, as it has been termed, continues wrapped in mystery; while its advance has never received a check, and no practical consequence deduced from it, other than that little which the farmer's own common sense and past experience has suggested. How humiliating is this lesson to science; how suggestive of the necessity of calmness, diffidence, and perseverance in its investigation! Had more of these ingredients been blended in the late numerous inquiries into this subject, the dignity of science would have been better up-

held, and the futility of human efforts to arrest the advance of the evil more quickly appreciated; and appreciated, too, not from sad experience, but from philosophic induction—by showing it to be the effect of a cause uncontrollable by human agency; a cause which I would hope that no one now can be so blind as not to admit, and which it will, partly, be the object of the following observations further to elucidate, namely, atmospheric contagion.

When the potato disease first excited alarm, and microscopic observers were busily engaged in minutely describing and classing the *fungus* or *animalcule*, or whatever it was which they gravely announced as the cause of the epidemic, you were kind enough to give insertion in the *Medical Times* to a short article or two of mine, containing a few brief remarks on this subject, with the inference of atmospheric contagion. Without pretending to say that such unpresuming compositions had any such effect, I had observed the opinion to gain considerable ground shortly after, that to a peculiar atmospheric condition could alone be satisfactorily attributed the cause of the potato blight, consistently with the phenomena developed in its rise; and during its course more extended observation confirms this view.

Whatever may be the physical properties of the atmosphere which surrounds our globe, and its relations to animal and vegetable existences, science as well as popular observation has confirmed the fact of its being subject to periodic changes coincident with particular periods of the day as well as of the year. The practical and observant physician has, from the days of Hippocrates down to the present, noticed the varying aspect of disease at various periods of the day; and the science of meteorology confirms the truth which simple observation first promulgated; and Columella as well as Martin Doyle was aware of the influence of the several seasons on the process of vegetation. Were the vegetable organization as well understood as the animal, and the relation in which it stands to physical and atmospheric agencies, the cause of the late potato epidemic would not have proved so difficult of discovery, nor the devastation effected by it matter of so much surprise. In the theory of atmospheric influence would be found as ready and easy a solution of the difficulties involved in its rise and progress as the same theory affords of the phenomena of cholera in man; and a more intimate acquaintance with its anatomy and physiology would supply, in the structural changes effected in the plant and the parts seized with the disease, in the order of succession with other concomitant circumstances, a ready and conclusive inference as to its cause.

I believe that the institution of an analogy between the potato disease and that to which horned cattle, more particularly, are subject first originated with myself. In a work subsequently published by Dr. Parker, of London, in which much learning is displayed, and ingenious but very inconclusive arguments in proof of a novel theory regarding the cause of the potato disease are brought forward, allusion is made to this analogy. In fresh-water fish, during the last year, I have observed, and I believe have been the first to announce, a fatal and no doubt epidemic disease to have prevailed. In the leech I have also noted a disease of a quickly-fatal character; and I have no doubt that, were other classes of the animal kingdom examined, a similar mortality would be found to have existed. The wheat and oat crop also suffered, but to a minor degree, as did all the species of fruit, which were, indeed, almost a total failure. The onion and the nut did not escape; and in all, vegetable as well as animal, analogous organs, viz., the respiratory, were those in which disease localized itself. The anatomical lesions in all were analogous and the same intractability to every effort of art equally characteristic of these various affections. The cause universally assigned of the disease among the cattle was atmospheric; but no analogy traced any connection between

the vegetable and animal disorders. It need not be offered as an objection to the idea of such a connection, that if the cause were in both instances the same, both animal and vegetable should suffer at the same time. Although chemical or any other kind of analysis cannot detect any differences in those conditions of the atmosphere which are universally admitted to produce specific diseases, differing in themselves, yet originating from the same source, the fact that such diseases are produced by atmospheric agency, and that they are in themselves essentially different, is sufficient evidence in proof of the truth of the opinion that there must be essentially specific differences in the conditions of the atmosphere, which produce correspondingly essential and specific effects. Thus may we admit a specific condition peculiarly hostile to the well-being of the potato; another to that of the cow; and, yet more, another peculiar in its influence over one vegetable, for instance, the onion, and yet innocent of any deleterious properties as regards the apple, &c. Indeed such an admission requires no stretch of imagination: for as each possesses a specific organization peculiar to itself, and specific physical properties, so must each possess specific powers of modifying or controlling specific agents; nay, yet further: individuals of the same species, as they differ from each other more or less by insensible and inappreciable modifications of their being or structure, which in animals we term idiosyncrasy, so must they differ in their resisting powers: for on no other principle can we explain to ourselves the immunity enjoyed by some individuals vegetable as well as animal, which quickly destroy others of the same family, and to which they themselves are exposed under precisely similar conditions. Witness, for instance, in a field of potatoes, visited during the last year and the preceding by the disease, the sound, full-developed tuber, flourishing in healthy maturity, beside others reduced to a pulpy, semifluid mass of putridity.

If Providence has been liberal of her blessings, she also seems to prove herself considerate in the infliction of her punishments. If she afflict the animal kingdom, she in mercy spares the vegetable; and if she strike the vegetable, she as surely spares the animal. Thus, when the grazier, some few years back, was plunged into despair and seemingly inevitable ruin by the unsparing mortality among his cattle, numbers of which a single night sufficed to prostrate, although in apparent health and vigour, the agriculturist's most sanguine hopes were realized in an abundant harvest; and when, a few years later, the agriculturist's turn to mourn arrived, for the ruin of the potato and a deficiency in the yield of his other crops, the grazier's stock flourished in health and increased in value. The atmospheric contagion in both instances reciprocally reacted upon each: it raised up the one as it struck down the other.

In the quantity of land under the potato in the present year, although not more than about the one eighth or tenth of the usual amount, we behold an evidence of the farmer's cupidity and love of speculation; buoyed up by the hope of a coming scarcity in the first instance, and, in the next, stimulated by the chance of an inordinate profit, he risks his capital, and the result is, that from the universality of these motives of gain, a larger tract of ground is under this article of diet than the past experience of the devastation effected by its disease would seem to warrant.

Although it is gratifying to know that no present symptom of a return of the malady has announced itself, it is not wholly unalloyed by fear, as we are just about the period when its invasion first took place last year. There is one consideration, however, grounded upon the previous remarks which leads me to infer that the potato will escape, if not entirely, at least to a considerable extent: it is a tendency manifesting itself to disease among the horned cattle precisely similar in many instances to that by which such vast numbers have been before destroyed; indeed, considerable apprehensions are enter-

tained, in certain localities particularly, that great losses must be sustained this year from this cause. On the other hand, I have witnessed appearances on the cherry-tree, in some localities, which subvert somewhat from my confidence in the happy maturity of the potato crop: these consist in a withering of the leaves and blasting of the embryo. Presuming, however, a failure of the potato this year—nay, even next, or even the year after—the above theory, if true, favours the hope, as it may be inferred, of its ultimate healthy condition and abundant supply. The idea of the necessity of propagating it from the seed, founded on the opinion of its having arrived to its extreme senectitude, is absurd, upon the same premises.

Such is a short summary of the conclusions to which an extended observation of late has led me. If the epidemic among the cattle gain ground (and I have no doubt but that it will), and the potato escape this year, can any more conclusive evidence, I would ask, be required or, indeed, afforded in proof of the existence of a very novel, at least unthought-of, connection between the two—a knowledge of which, if found verified by future observation, must prove of immeasurable practical value to the agriculturist and the grazier, and a fruitful subject of serious and interesting investigation to the scientific inquirer?

July 1.

JOHN ALEXANDER MORRIS.

LAW AND MEDICINE.

[To the Editor of the Medical Times.]

SIR,—I beg leave to direct your attention to an important decision which has taken place in the Grimsby County Court; and, in reference to the outrageous piece of injustice perpetrated on the medical practitioner, I beg to ask the following questions:—

Is not the decision legally wrong?

Is there any law in this country which can sanction one man calling another an impostor, because the latter, not being a M.R.C.S., styles himself a surgeon?

Is it not quite possible that a man may be a very good surgeon, without being a M.R.C.S.?

Is not the converse of this equally possible, that a man may be a M.R.C.S. without being a surgeon?

And is it not also possible, and does it not appear from the above judgment, that a man may be a "barrister" and a "judge," and yet know as little of *law* as Mr. Burnham is gratuitously supposed to know of *surgery*?

Mr. Burnham being L.S.A., and most likely pleading that fact, is not he entitled to recover for "attendance and medicines," although he may, like all his brother-practitioners, style himself surgeon?

If Mr. Burnham had been a M.R.C.S., would he have been legally in any better position for recovering the debt than he was?

Has Mr. Burnham no remedy as well for being insulted in open court, as for the loss of debt and costs?

Would it not have been quite as legal, if the plaintiff had been nonsuited for not being a Fellow of the Astronomical Society?

Carrying out this decision to its full legal consequences, can an artist recover a debt if he is not a member of the Royal Academy? or a druggist, who is not a member of the Pharmaceutical Society? or any other professional person or tradesman, who is not connected with the chartered body which represents his trade or profession?

And, lastly, are not the two attorneys who pleaded before this learned judge, quite as much impostors as Mr. Burnham, not having been called to the bar?

I think you will consider the importance of the subject to the profession sufficient to warrant my troubling you with this communication; and remain, Sir,

Your most obedient servant,

July 10.

L. S. A.

The following is the case referred to:—

IMPORTANT TO THE MEDICAL PROFESSION.—GRIMSBY COUNTY COURT.—BURNHAM V. WARBURTON.—This was a case in which the plaintiff, calling himself a surgeon, sought to recover of the defendant the sum of £2 11s., for attendance and medicines supplied to a young female by order of the defendant. Mr. C. Ingoldby, who was attorney for the plaintiff, having stated the case, Mr. Brooks, attorney for the defendant, asked the plaintiff whether he was a member of the College of Surgeons, to which he answered—"No." Mr. Brooks then took an objection to the plaintiff's suing to recover a debt in the capacity of a surgeon, as stated both in the bill and the summons, when on his oath he admitted that he was not a surgeon. The judge admitted the force of the objection, as a surgeon and an apothecary were distinct and separate departments of the profession; and for a man to assume a title to which he had no claim—had not passed through studies and examination to entitle him to it—but who sought to recover debt under that assumed title, was a fraud upon the public, and he must give judgment for the defendant.

FRENCH MEDICAL REFORM.—There is now existing a great agitation among the professors of the Faculty of Medicine, on account of the question of *concours*. A certain number are of opinion to address the Chamber of Deputies, by the medium of the Minister, a protestation against the vote of the Chamber of Peers. This resolution meets a very great opposition on the part of several professors who have pronounced against the *concours*. The latter are not the least eminent, or least influential.

LIFE-ASSURANCE OFFICES AND "TIE FEES."

[To the Editor of the Medical Times.]

SIR,—Much has been said and written upon this subject, as I think, unnecessarily. From the numberless communications that have appeared in the medical journals, it would seem that the profession is determined to decide which party is liable for payment—the insurers or insured. Now, I take it, this is interfering with that which does not concern us, "ne autor ultra crepidam." Provided always the medical referee gets his fee, it matters not to him whence it comes. I never heard of a physician refusing a fee because it came not from the sick man's hand. If I swear an affidavit, the fee is not thrown in my teeth because another ought to pay it; neither, if another tenders it, is it refused because I ought to pay it: the party swearing me receives it, and that is his business; it matters not to him who is most interested in the said affidavit. Perhaps I am about to propose a somewhat novel opinion respecting such matters. If an insurance-office applies to me, enclosing a fee, I consider myself bound to act on their behalf, and reply in such a manner as shall best serve their interests. If, on the contrary, I receive an application and a fee from my patient, I am bound to look to his interests, and avail myself of all the loopholes of evasion of which the report admits, up to a *suppression veri*; the most honourable profession (the bar) furnishes me with a precedent for such a course. If I see an advocate, he does the best he can to acquit me; that is his business: though he might at the same time be in possession of that which would, without doubt, convict me. I contend, therefore, instead of quibbling about who is to pay, the medical referee should wait and see by whom he is retained. It might be said that the questions are too pointed to admit of evasion. I never saw such as would prevent me from "putting in" a bad life, with all their point: *ex.gr.*, "Is the life such as, in your opinion, might be insured without more than the average risk?" From the loose way of obtaining information gratis, I apprehend the average risk to be very great; therefore, I can conscientiously reply—Yes.

Would you, Sir, in your sober senses, think of arguing with a highwayman that taking your purse was discourteous and dishonest? Yet he

(we have it on authority) "steals trash." How much more fruitless, then, such argument with the would-be pilferer of your braincase: there is but the one maxim to pursue—*Cohite qui cohite*.

It might be asked, when applications come without a fee from either side, as is too often the case, what is to be done? Why, like a disinterested man, split the difference: take one half the sheet to light your pipe, and use the other as an envelope (it always has a stamp). Medical men have this matter more in their own hands than they think. If the insurance-offices were disposed to facilitate the business for all parties, I would suggest that to the end of the report should be attached a blank form of receipt for one guinea, without the filling up of which by the referees all the rest should be void.

There are certain offices having the word "Medical" interwoven with their titles. I can only say that the single instance in which I was what is called "regularly done" (*pro. tem.*), was by one of these; and, on applying for my fee (as the party acting for the office), got a polite intimation of a "wish that I might get it"—a wish, by the way, which will be realized. There are medical men attached to all the offices who clearly know right from wrong. For myself, I am an advocate for what is called "self-dependence." I do not like your broken reeds, and would be sorry to lean upon the promises of a profession which I fear never did and never will uphold its own rights, honour, and dignity.

I am, Sir, your obedient servant,

Quid pro Quo.

BEDFORD GENERAL INFIRMARY.

[To the Editor of the Medical Times.]

SIR,—I have to beg the favour of your correcting an error, into which you have been led, no doubt, by an incorrect report of the proceedings at the recent election of a physician to the Bedford General Infirmary.

I graduated, not, as stated in your article, a fortnight before the election, but in August, 1846, without any view to the office I now hold, the vacancy of which was caused by the melancholy suicide of my predecessor. I would also, with your permission, endeavour to remove an impression apparently prevailing, that the diploma of the University of St. Andrew's may be obtained by payment of certain fees, and submitting to a merely nominal examination. With very few exceptions, the candidates who present themselves at St. Andrew's have already passed examinations elsewhere, and been declared competent to practise; and yet the proportion of the rejected is very large, averaging one in five. I believe that at the London University only is it so high.

The examination I underwent was certainly as extended and searching as those of the London College of Surgeons and the Apothecaries' Society together, and was conducted in a fair and gentlemanly manner by men of extended reputation in their various departments of science.

I have the honour to be, Sir,

Your obedient servant,

GEORGE DIXON HEDLEY.

Bedford, July 11.

MEDICAL REFORM.

[To the Editor of the Medical Times.]

DEAR SIR,—I am happy to observe, by the *Medical Times* of the 19th, that Mr. Wakley's measure of Medical Reform is no more. Yet we can scarcely say with confidence, *requiescat in pace*, for he threatens to move at a future time for the reappointment of the committee then sitting upon the subject. Now, lest that or any other such imperfect bill may be again introduced into Parliament, and unexpectedly passed through the House, would it not be well to endeavour to establish a great scientific corps in London in imitation of the French Congress assembled in Paris in 1846, which would com-

municate amicably with the Government, and, for the guidance of the State, lay down a solid foundation of true reform: for instance, a corps of delegates representing the medical profession of every grade, from all parts of the united kingdom, which would collect information from all quarters, and by their united experience and intelligence develop the principles of a broad universal organization. Without such a united effort, no system of reform can succeed; and without such assistance, Government will ever want that enlightenment upon medical subjects by which alone useful legislation can be ensured. The French Minister hailed in the most cordial manner the aid of the Congress, attended their deliberations, and upon their conclusions based the project of law lately discussed by the Chamber of Peers. If the medical faculty of France had not thus nobly worked together—if the physicians, surgeons, and apothecaries had not thus combined; if they had acted in an isolated manner as we do—their common complaints would have remained undressed, abuses would have continued, and their divided efforts would have been confined to the opposition of those wild and mischievous schemes of which we have had example in the measures of Mr. Wakley and Sir James Graham. The Congress held their sittings only fifteen days; yet it was one of the grandest manifestations in the history of medicine, and proves the mighty power of intellectual union in overcoming difficulties that would have baffled the mental resources of any individual mind. Every department of medicine had its representatives there—physicians, surgeons, apothecaries, and veterinary surgeons. In the *sance* of inauguration, M. Serres thus alludes to the necessity of union:—"En effet, vous devez comprendre et vous avez compris que tous ces maux qui nous affligent, ne seraient jamais soulagés ou guéris dans l'impuissance de notre isolement, que toujours vos plaintes et vos réclamations seraient stériles et se perdraient dans le tumulte et les préoccupations sociales, tant qu'elles resteraient individuelles et localisées, que vos vœux ne seraient écoutés que lorsqu'ils se produiraient comme l'expression d'une manifestation générale librement convoquée, librement consentie et qui réunirait la double garantie du nombre et des lumières."

Legislators in England are not more enlightened than the French upon medical subjects; nor can the legislature of any country enact efficient laws without first thoroughly understanding the nature of what is brought under its consideration. Sir James Graham's Bill was a melancholy instance of the rashness of a man, however intelligent, attempting to frame a law without being sufficiently acquainted with its objects. Legal measures, under such circumstances, are political quackery. As well might a man prescribe for disease who is totally ignorant of the human economy. The sources from which correct information can be attained of the details of the medical profession exist almost exclusively within the precincts of the profession itself; and that is the reason why Monsieur Orfila, Dean of the Faculty of Medicine in Paris, is associated with the French Government as a member of the Council of Public Instruction. There are also physicians and chemists in the Chamber of Peers. A law is changed or amended when its evils and imperfections are ascertained, and it is by a knowledge of the latter that we advance in legislative improvement. The English Government is completely destitute of the information necessary for medical administration. We have no member connected with the Ministry—no member in the House of Peers; and in the House of Commons I may say there is but one, who, from his various duties foreign to medicine, can be scarcely expected to possess that practical detailed knowledge which the consideration of medical reform requires. Medical policy engages the public mind much less than any other political topic; and it is to be deplored that, even amongst the influential and educated portion of the community, very little, if any, correct information exists with regard to the vicious constitution

of the medical profession. Medical subjects are considered as only suited to the sheets of the medical press; and, from their having been long confined to medical works and periodicals, the great majority of the public has been left in complete ignorance of the real condition of our medical system. Public opinion has not been legitimately brought to bear upon it; abuses upon abuses have been silently allowed to accumulate; so that eventually a noble science, identified more than any other with individual and general happiness, has become a confused indescribable chaos, for which there is no other remedy than a complete reorganization. The public press seldom or never touches upon medicine, though teeming with every other information. Yet with what assiduity that same press culls from the proceedings of judicial courts every scandalous disclosure of private life. Look at the puffs of charlatanism which every day disfigure its pages and degrade its character; those filthy, obscene, and disgusting advertisements, to which the public press is ever open, by which a journal, instead of being a source of amusement and instruction, becomes unfit for the eyes of innocence; and, instead of forming an interesting appendage to every day's literary occupations, cannot, without very great moral danger, be admitted into the circle of private families.

Descartes says:—"Si l'on pouvait traîner quelque moyen de rendre les hommes plus sages et plus ingénieux, ce ne serait que dans la médecine." But the doctors themselves will not get credit for their reformatory exertions. That good and generous feeling which actuates them in the free and constant discharge of unnoticed and unremunerated services will not be supposed to expand itself into the magnanimous desire of ameliorating the physical and moral nature of the human race. In England, where legislative measures are formed under the influence of public opinion, it is scarcely to be wondered at that medical policy has but little engaged the consideration of legislators, when the public at large, from ignorance of the subject, never raised its powerful voice in favour of an improved system. The public are unaware of the insidious manner in which their dearest interests are compromised; hence their indifference. The representatives of the people must be first impressed with the importance and necessity of medical reform, and fairly instructed in the sad state of medical administration, before they will substantially lend their aid to the profession to extricate itself from its present position. The profession in England requires the assistance of power, as in France. It is too much divided in itself to effect a change, unless the interests of all parties be calmly and liberally debated—unless the fragments which compose it be brought together by some happy understanding. The result of their deliberations may prove disagreeable to some portions, but the opinion of the majority ought to be considered paramount. Government, upon its own responsibility, cannot succeed: for, besides their incapacity upon this particular question, medical institutions have been so long and quietly permitted to govern themselves, to enact by-laws, and follow whatever plans they pleased, uncontrolled in the slightest degree by superior authority, that now interference on the part of the State assumes the aspect of tyranny, and yields to resistance.

The profession has proved itself unequal to the task of reform, and the Legislature, in like manner, has failed. Then let us imitate our Gallic neighbours, by instituting a grand combination of the profession and framer, not servile in any way to the former, and worthy the dignity and wisdom of the latter,—a combination of intelligence, which will have the double object of the public welfare on the one hand, and on the other, that of placing the science of medicine on a sure philosophic basis, becoming the enlightenment of the age. In short, let Medical Reform become, what it ought to be, a great national question, for it interests every man, from the prince to the beggar.

GOSSIP OF THE WEEK.

The bill of Sir James Graham, which gave a *carte blanche* to every one to practise medicine, was not only degrading and injurious to the medical profession, but was insulting to the intelligence of the English people. That measure generally deserved well the talented reprobation of the *Times*. Yet I fear that the manner in which one good feature of that measure had been received and attacked by the *Times* in 1844 has greatly tended to interfere with the progress of Medical Reform, and discourage future statesmen from interesting themselves with the subject. The principle of his bill, which would divest medical institutions of their irresponsibility, and establish a central surveillance over them, was good in the abstract. For surely, when the Legislature grants to corporate bodies the privilege of licensing men to enter into a career in which they are capable of doing much good or the most direful mischief—surely that Legislature has a right, and owes it as a duty to the country, to rigidly exact from such corporations, rules and regulations commensurate with the serious duties of their graduates. Can the principle of competition advocated by the *Times* be safely applied to medicine? It scarcely can, if we contemplate the evils that will be entailed upon society by even one badly regulated medical institution, even one incompetent person. The members of such a body mingle in with society, whose safety is placed in the hands of the Crown; and, however that licensing body may afterwards improve, whether from motives of humanity, shame, or a spirit of emulation, the errors of the past cannot be repaired; human life, sacrificed to ignorance, can never be recalled. One great and manifest evil arises from that competition: the discord which is thereby engendered among practitioners who inherit the ideas of their *alma mater*. In every part of the united kingdom we find disunion proceeding from such a cause. Very few of the faculty are upon intimate terms. The greater the distance between them, the more friendly their relations. Each has his party, and the more disgraceful means are often resorted to to injure the reputation of a professional brother. An unfortunate illustration of the proverbial differences with which people are fond of characterizing the profession may be found in every locality, however small; and this want of agreement impedes the progress of science by preventing intellectual co-operation, and deprives the public at large of the benefits of multiplied experience. A medical machine, says Cabanis, like other machines, requires harmony in all its parts.

I have the honour to remain, dear Sir, your obedient subscriber,

S. S. MORIARTY.

Dieppe, Grande Rue, 132, July 5.

THE VALUE OF THE APOTHECARIES' LICENSE.

[To the Editor of the Medical Times.]

SIR,—A few weeks since you honoured me by inserting a communication relative to the neglect of the Apothecaries' Commission in not prosecuting one of I who assumes a position as surgeon and apothecary, which he has not the slightest right to hold; and, if you will permit me further space, I will now enter more fully into the particulars of the case, convinced that good might be done to our cause by fairly holding up to public view even one glaring instance of the maladministration of an important act, by a trading corporate body. Virtually I believe the act has become a nullity, at least I can derive no benefit from it, though I have devoted no few hours towards attaining "the full benefit of the act" against —.

It may be asked, why has this man remained so long unmolested? The context will show. I came to this place in 1844, single-handed, to work out a practice, but I soon discovered the manor in the out-districts was most extensively poached

on by this individual; he was attending, undisturbed, most of the farmers' families—the women in their accouchements, the men in all diseases. No one seemed to question his qualification to practise, for he sprang up insidiously, like a mushroom on a murky night, lucky to come in, just at the moment, when ago began to diminish the activity of Mr. Peter Best, then holding all the practice of the neighbourhood, and now, perhaps, the oldest practitioner in England. An apprenticeship of a year or two with a man at — was all the medical education — ever had; a hasty marriage compelled him to break his indentures, and he came to — almost a beggar, and even drove a van. Physic, however, was wanting; so, with the smattering he had, he left the "whip to drive a practice." One patient begat another; right or wrong, he went blundering on, curing or killing, no matter what disease beset his patient. On the proceeds he is enabled to keep up an establishment; a horse and gig, on which is blazoned forth " — surgeon, — — —." The county coroner used to call him in, and his evidence has been received by juries, under the full impression that he was qualified according to law. Till I strung my bow and shot my arrows at him, no one ventured to the fight: he was the Goliath of Gath, and ruled the empire of physic round about. On the many parties, whose names I transmit, he has attended since I have been here. I grew tired of collecting evidence against him, or I might augment the list to fold. He also attends "an Odd Fellows' Club, held at —'s, in —; and three or four at —, held at public-houses; the treasurers, or any one of these parties, might be summoned to give evidence against him, for I have furnished the society with the requisite evidence." After having taken the initiative against — at the express instigation of the society, it does make me look such a fool for the matter to be left in *status quo*—he continuing to practise, and I looking on in evident defeat. Here there is not the possession of a college diploma to gain the sympathies of a jury; to enter the profession he must begin *de novo*. Hitherto his career has been amenable to the laws of the land; conviction would easily follow indictment.

A village barber hangs out a pole to show the nature of his occupation; but a blunt razor or an unsteady hand drives away his customers. A village quack seduces his victims by styling himself "surgeon;" but his honeyed words sweeten the draught; and the patient, swallowing both from the charlatan, falls into his premature grave. The keeper of a beer-shop is fined £20 for selling spirits without a license; there is no trouble in obtaining conviction; and why should we have, when the lives of the public are at stake?

Let us awaken from our lethargy. Our diploma is a false shield; let us fashion fresh defences for ourselves; let us institute a prosecution society, and contribute largely towards its support; let us have a high legal adviser to defend the members. We must not stand as we are; an instance like this is sufficient to prove the instability of our position—our tale of woe—the want of value in our diplomas. We have sacrificed the health of youth to obey the supposed mandates of the law; we have burnt the midnight oil in vain; we have scattered thirty golden guineas to the winds—now, in the summer of our lives; and, if we do not screen ourselves, innumerable — will come to deprive us of the fruits of our labour.

I remain, Sir, your obedient servant,

ALFRED EBSWORTH,

Surgeon to the Bedford Union Workhouse and Bulwell District,

Bulwell, July 11.

[Mr. Ebsworth has serious causes of complaint; but the law of libel would punish us with some severity if we did him full justice in their publication.—ED.]

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma of this college, were admitted members at the meeting of the court on the 25th ult., viz.:—Messrs. Theophilus Taylor, Hereford; William Hand, Northwich, Cheshire; Horatio Harrison Smith, Ramsgate; Robert Horne Kemp, Brighton; Charles William Latham, London; Edward Vye, Ilfracombe, Devon; James Tarzwell, Dorchester; William Leyson Thomas, Neath, Glamorganshire; Augustus Grant, Thayer-street, Manchester-square; and Arthur William Watson Smith, Chertsey, Surrey. At the same meeting of the court, Mr. Nicholas Littleton passed his examination for naval surgeon. This gentleman is a member of the college, his diploma bearing date December 22, 1840.—July 2. J. O'Brien, J. Day, H. J. Rice, T. Park, F. Mason, C. D. R. Symons, G. A. H. Hepworth, M. Thomas, W. E. Hamblay, W. Mott, A. Blyth, W. G. Cort, H. Crisp, E. W. Lowe, and J. F. Badley.—July 9. Mr. Horatio Philip Harris, Leominster, Herefordshire; Mr. Louis Truefitt, Bunwood-place, Edgware-road; Mr. John Tudor, Blanford-square, Regent's-park; Mr. John Rogers, Worcester; Mr. John Farmer, Hereford; Mr. Joseph Burgoon, Bucklersbury; Mr. Harry Frederick Barnett, Bradley, near Bromsgrove, Worcestershire; and Mr. Joseph Fayer, Royal Ophthalmic Hospital, Charing-cross. The next examination for the Fellowship of this college will take place on Tuesday and Thursday, the 3rd and 5th of August.

ROYAL COLLEGE OF SURGEONS.—His Royal Highness the Grand Duke of Saxe Weimar, accompanied by his suite, again visited the Hunterian Museum of this College on Saturday morning, and remained upwards of two hours inspecting its valuable contents, which were explained to his Royal Highness by Professor Owen. On departure the illustrious party expressed the great gratification they had derived from the visit.

APOTHECARIES' HALL.—Gentlemen admitted members June 24: Herman Henry Tribe, John Riggs Miller Lewis, George Augustus Jeffery, William Jones, George Hawkesford, William Crosby, Thomas Clayton Mourilyan, John Dickson, John Griffiths Doidge, Charles Broughton, and John Taylor Rowland.—July 1: James Henry Thomas Vaughan Hughes, Joseph White, Thomas Rhodes Armitage, and Francis William Merry.—July 8: William Henry Cook, Edmond Archer, and Michael Hoole Ashwell.

WAR-OFFICE, June 25.—Hospital Staff: Deputy Inspector-Gen. of Hospitals Henry Franklin to be Inspector-Gen. of Hospitals, vice John Frederick Clarke, M.D., who retires on half-pay; Deputy-Inspector Gen., with local rank, John Kinnis, M.D., to be Deputy-Inspector-Gen. of Hospitals, vice Franklin, promoted; Staff-Surg. of the First Class Andrew Fergusson, M.D., to be Deputy-Inspector-Gen. of Hospitals, with local rank, vice Kinnis, appointed Deputy-Inspector-Gen. of Hospitals; Local Deputy-Inspector-Gen. of Hospitals Sir James Pitcairn, M.D., to be Deputy-Inspector-Gen. of Hospitals; Deputy-Inspector-Gen. of Hospitals Sir James Pitcairn, M.D., to be Inspector-Gen. of Hospitals, with local rank.—July 13.—3rd Dragoon Guards: Richard Carmichael Bourne, gent., to be Assist.-Surg., vice Mapleton, promoted to the 40th Foot.—13th Light Dragoons: Assist.-Surg. George Thomas Woodman, M.D., from 48th Foot, to be Assist.-Surg., vice Sall, promoted in the 5th Foot.—5th Regiment of Foot: Staff-Surg. of the Second Class William Ord Mackenzie, M.D., to be Surg., vice Duncan Henderson, M.D., who retires upon half-pay; Assist.-Surg. William Sall, M.D., from 13th Light Dragoons, to be Surg.; Assist.-Surg. William Battley, from the Staff, to be Assist.-Surg.—21st Foot: Assist.-Surg. Francis Charles Annesley, from 61st Foot, to be Assist.-Surg., vice Clark, who exchanges.—26th Foot: Assist.-Surg. James Johnston, M.D., from 71st Foot, to be Surg., vice Stewart,

appointed to the Staff.—40th Foot: Assist.-Surg. Henry Mapleton, M.D., from 3rd Dragoon Guards, to be Surg., vice M'Munn, promoted on the Staff.—61st Foot: Assist.-Surg. Frederick Hobson Clark, from 21st Foot, to be Assist.-Surg., vice Annesley, who exchanges.—71st Foot: John Andrew Woolfrees, gent., to be Assist.-Surg., vice Johnston, promoted in the 28th Foot.—Hospital Staff: Surg. Robert Andrew M'Munn, M.D., from 40th Foot, to be Staff-Surg. of the First Class, vice Andrew Fergusson, promoted. Surg. John Stewart, from 26th Foot, to be Staff-Surg. of Second Class, vice Copeland Gratton, M.D., who retires upon half-pay. Staff Assist.-Surg. George Williamson, M.D., to be Staff-Surg. of the Second Class, vice Mackenzie, appointed to the 5th Foot. Assist.-Surg. Sandford M'Vitty Lloyd, M.D., from the 62nd Foot, to be Assist.-Surg. to the Forces, vice Williamson, promoted.

NAVAL MEDICAL PROMOTIONS.—Surgeon: Dr. John Drummond, to the rank of Deputy Inspector of Hospitals and Fleets.

M. Cassimir Broussais, Chief Physician of the Military Hospital at Gros-Caillon, has just died at the age of forty-four. His funeral took place on Wednesday, in the midst of a numerous concourse of members of the profession. A deputation of the *agregés* of the school, in full costume, having at their head the Dean, who represented the faculty; the professors and pupils of Val-de-Grâce, as well as a great number of surgeons from the garrison of Paris, came to pay the last token of respect to him who had been, during twenty years, one of their most esteemed colleagues, and one of their kindest masters. Several orations were pronounced over the tomb by MM. Alquié, Larrey, and Marchal (de Calvi), in the name of the professors of Val-de-Grâce; by M. Barth, in the name of the Faculty of Medicine; by the Surgeon-in-Chief of the garrison of Paris; and by a pupil of Val-de-Grâce.

Dr. Laugier, surgeon of the Hôpital Beaujon, has just been appointed surgeon to the Hôpital la Pitié, in the place of M. Lishiane.

SCURVY.—This disease has appeared in Paris. Several cases have been brought to the central bureau of the hospital.

NEW INSTRUMENT FOR ETHERIZATION.—M. Jules Roux, of the Naval School of Medicine at Toulon, has considerably simplified the apparatus for the etherization of ether. An ox bladder, or a pig's, covered by any thin fabric, and forming together a bag, drawn together by a sliding string; a hole in the side of the bag, encircled by a wooden bowl, and perfectly closed by a small stopper of wood, which can be taken out at pleasure: such is the new apparatus of M. Jules Roux. They place up the bottom of the bag a sponge dipped in ether, and then enclose the nose and chin of the person to be etherized.

MEDICAL SCHOOLS OF THE UNITED STATES.—By the report made to the National Medical Convention, at its meeting in May last, it appears there are thirty-seven recognised schools of medicine; the oldest of which is the medical department of the University of Pennsylvania, which department was founded in 1765, and the last established is that of the Western Reserve College, established in 1811.

NAVAL MEDICAL APPOINTMENTS.—Surgeons.—John Clarke, to the Avenger, vice Steele; Frederick Martyn, to the Innam.

OBITUARY.—On Saturday, the 10th inst., at the house of his son, Paddington, William Hopeful Lerew, Esq., surgeon, aged 57.

POLICE.—BOW-STREET.—On Wednesday Henry Johnson, the young man who stood charged with forging a certificate of examination at the Apothecaries' Hall, was fully committed for trial at the Old Bailey. It will be remembered that the prisoner, failing to pass his examination, procured a genuine certificate and got a *fac simile* engraved from it. By an understanding between the engraver and the Apothecaries' Company, he was apprehended, with both the original and forged document in his possession.

The Alarm, 26, Captain Jack, had left Vera Cruz for Halifax, by the last advice. Her crew were very sickly, and dying in twenties at the hospital. She was at Havannah on the 8th of June, and called off Bermuda on the 19th. Dr. Howler, surgeon of the Alarm, has come home invalided.

EFFECTS OF QUACKERY.—A female died in Rochdale, on Saturday week, from taking Morison's pills. On the day she died she swallowed two boxes of them, each containing 132 pills.

THE BRITISH MUSEUM.—Mr. J. Payne Collier has been nominated secretary to the commission for inquiring into the management of the British Museum. A better appointment could not have been made. Mr. Collier has devoted many years to literature, especially to that of the olden time; but, besides being "dear" "black-letter" lore, he has those habits of application and business which peculiarly fit him for his new office.

INTERESTING GEOLOGICAL DISCOVERY.—M. Erdmann, Professor of Geology at the imperial University of Dorpat, who is now travelling in the south of Russia, has just discovered in soil, situated to the south of Odessa, a great many skeletons and fossil bones of animals, all of enormous dimensions. The skeletons were about eighty-three in number: six elephants, one rhinoceros, two of the ox-kind, four stags, one antelope, sixty-one bears, two yenas, two dogs, three cats, and one ruminating animal of an unknown species. These skeletons, as well as the bones, were found immediately under a thick calcareous stratum. The discovery made by M. Erdmann is so much the more remarkable, as, till now, few or no remains of the antediluvian animal kingdom have been found in Russia.

MESMERISM.—The *Phare de la Manche* mentions three new operations, performed at Cherbourg, upon patients, during magnetic sleep, with complete insensibility, by M. Loysel, assisted by M. Fleury. One of these operations, the only one that the journal mentions with any details, consisted in the extirpation of a very large mass of glands and ganglions, situated upon the side and back part of the neck. The journal cites as witnesses of these operations a great number of persons, among whom were several physicians and principal inhabitants of the place.

MORE POISONINGS IN NORFOLK.—On Monday last the inhabitants of Stokeferry were alarmed by a report that a diabolical attempt had been made on the lives of the family of Mr. John Mayes, butcher, of that place. On inquiry it was found to be but too true; for breakfast was barely over before each and all who partook of the tea, of which it chiefly consisted, were taken suddenly and violently sick, with acute burning pains in the throat and stomach. Of these, perhaps, Mr. Mayes himself was the greatest sufferer, though all were more or less affected. At first it was thought to be something in the teapot, but on examination by Mr. H. B. Steele, the surgeon of the place, the presence of arsenic in a large quantity was easily detected in the kettle from which the teapot had been supplied; this kettle Mr. Steele immediately secured. Of course prompt and, we hope, effective measures were resorted to; for the whole of the sufferers (seven in number) were stated to be better. We regret, however, to add that the effects of this horrid act have been visited on an eighth person, Mrs. Tindal, of the Crown Inn, who, calling on her neighbour, Mrs. Mayes, unguardedly swallowed a small quantity of the water from the teakettle (this was before it was known or even suspected to contain poison), and has ever since been in a suffering, not to say alarming, condition. Had she, like the rest, taken enough to cause immediate reaction, she might possibly have suffered less; for the ultimate safety of the intended victims, if saved they are, may be said to owe to the strength of the poison; and thus the very bane becomes the antidote. Measures are being taken by the police which, it is hoped, will soon afford a clue to the perpetrator of this vile attempt.—*Essex Herald*.

AND OF M. PARISOT.—Literature, and in Royal Academy of Medicine have just experienced an irreparable loss in the person of M. Parisot, in the full exercise of his mental faculties and usefulness, in his 77th year. The numerous concourse of physicians, learned and literary men, artists, and people of fashion, who eagerly rendered the last honours to the celebrated perpetual secretary of the academy, testifies the deep sympathy he had obtained from all classes of society. His death has caused general grief, and has left in the academy a void which will not easily be filled up. Several orations have been pronounced over the tomb of Parisot, in the name of the Institution, the Academy of Medicine, the Council of Health, and his numerous friends.

ALTERING A DIPLOMA.—A curious trial has lately occurred of an apothecary of Graham's-town, named E. T. Taylor, who was accused of the commission of forgery in the alteration of a diploma granted to him by Governor Sir George Napier to exercise the profession of apothecary and wholesale chemist by inserting the word "surgeon." Mr. Ebdon defended the accused party at great length and with much ingenuity; but he was, nevertheless, found guilty, and sentenced to six months' imprisonment with hard labour.

AMERICAN NATIONAL MEDICAL CONVENTION.—On the first Wednesday in May last a National Medical Convention assembled at Philadelphia, to deliberate on the means which should be adopted to improve medical science; to increase the usefulness, to elevate the character and standing, and to protect the interests of the profession.

TANNATE OF IRON IN THE TREATMENT OF CHLOROSIS.—Dr. Benedetti asserts that the tannate of iron is the most efficacious of all remedies in the treatment of chlorosis. In evidence of this he cites cases from his own practice and from that of Dr. Majocchi, affirming that the treatment by the tannate of iron is successful in from twelve to twenty-five days, according to the severity of the case.—*Bull. delle Sc. Med.*

MORTALITY TABLE.

For the Week ending Saturday, July 10, 1847.

Causes of Death.	Total.	Average of 5 Summers.
ALL CAUSES.....	282	940
SPECIFIED CAUSES...	880	935
Zymotic (or Epidemic, Endemic, and Contagious) Diseases.....	215	226
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable Seat	102	103
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	156	157
Diseases of the Lungs, and of the other Organs of Respiration	195	226
Diseases of the Heart and Blood-vessels.....	21	25
Diseases of the Stomach, Liver, and other organs of Digestion	91	94
Diseases of the Kidneys, &c. Childbirth, Diseases of the Uterus, &c.	6	8
	11	10
Rheumatism, Diseases of the Bones, Joints, &c. ...		
Diseases of the Skin, Cellular Tissue, &c.	3	3
Old Age.....	50	50
Violence, Privation, Cold, and Intemperance.....	23	

No. 406.

SUMMARY.

JULY 24.

Foreign Practice; reported by A. MARK WICK.

Tuberculation of the Bronchial Glands, and Pathology of Dropsies

ORIGINAL LECTURES—

Clinical Observations on some of the more Frequent Diseases of Children, by W. H. WILLSHIRE, M.D. 435

On the Physical Phenomena of Living Bodies, by Professor MATTEUCCI, of Pisa 436

MORTALITY TABLE 443

ORIGINAL LECTURES.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILLSHIRE, M.D. (Edin.), M.B.S., Physician to the Royal Infirmary for Children, &c.

(Continued from p. 408.)

GENTLEMEN,—I shall continue to-day the subject of that interesting disorder, *tuberculous meningitis*. You will remember that I told you you would have to be upon your guard, in the diagnosis of this affection, that you did not regard the vomiting and constipation as evidences of primary disease of the gastro-intestinal apparatus, and treat the disorder accordingly. To-day I shall particularly draw your attention to some points of differential diagnosis. The first point for you to bear in mind is, that you may have slight febrile exacerbation in a child, together with heat of head, headache, increase of the special sensibilities, and derangement of the digestive organ—in fact, the first series of symptoms in the formidable affection I am speaking of—and yet, undoubtedly, the child may not necessarily labour under tuberculous meningitis. It is suffering under cerebral congestion, however, and no one can tell how soon such congestion, in a scrofulous child, may be followed by the disorder you will have so much reason to dread. So that, whenever such symptoms occur, and are evidently not secondary upon gastro-enteric disturbance, you must immediately pay attention to the important organ in disorder, and consider the brain as primarily in fault. So, also, if such symptoms intervene in the course of pneumonia, hooping-cough, remittent and other fevers, &c., although the disturbance of the cerebral circulation is secondary, yet the brain must be therapeutically treated. Sometimes what we may call simple cerebral congestion—the forerunner of simple acute meningitis, if the former were to continue in progress—may appear in the child; and this will demand equal care and attention, although it might not be followed by the tuberculous disorder, but by simple acute inflammation of the brain and its membranes. The only difference would be that the treatment in the one case is to be more depletory than in the other, as you will be sure of from the difference of the symptoms of the two congestions. In the simple acute congestion the accession is rapid, the face flushed, and there are glistening and suffusion of the eyes. Convulsions, jactitation, or even temporary paralysis, soon come on: in fine, you have a rather subdued exemplification of the early stage of true simple meningito-encephalitis. In the congestion which would be followed by the granular deposit, the accession is not so rapid, the symptoms not so severe, the face not so flushed, and excitomotor phenomena not so quickly occurring.

In simple acute meningitis, chiefly liable to be

confounded with the tuberculous variety in the second stage, you will have the accession very acute, all the symptoms intense, and the headache and agitation extreme; the febrile erethism very considerable, the vomiting of bilious matter not necessarily complicated with constipation, and coma rapidly coming on. The aggravation of the disorder is quickly progressive, and death very soon closes the scene. In *tuberculous meningitis*, the accession is not acute, but often very insidious, the primary symptoms not being severe and grave, except the vomiting, and which is accompanied by constipation. Generally the intellectual functions are normal, save in their gradual torpidity as the disease progresses. The course is comparatively slow, irregular, often very much prolonged.

Secondary simple acute meningitis is preceded by well-known primary symptoms of a special disorder, such as an eruptive fever, &c. It is not necessarily preceded by constipation, but often by active diarrhoea; sometimes by general anasarca or acute local inflammation of the chest, abdomen, &c., with deficient secretion of urine, and with high fever.

Meningeal apoplexy and cerebral hemorrhage can but rarely tend to hinder your diagnosis, although you will find a very interesting case in Rilliet and Barthez, of a girl who died after exhibiting the symptoms of the tuberculous disorder—some other symptoms, however, being superadded; and after death, a large clot was found in the left optic thalamus. The comparative rarity of these hemorrhagic affections, the very great irregularity of their symptoms, and the very early superposition of convulsions, will help to assist your diagnosis. I may refer you, however, to the writers I have named.

Hypertrophy of the brain is more likely to be confounded with chronic hydrocephalus, in some of its forms, than with our present malady, except, perhaps, in those cases alluded to by Mauthner, where the hypertrophy assumed an active character in consequence of the cranial parietes not yielding to the rapidly increasing growth of their contents, and in which the symptoms were those of active cerebral disorder and of compression. But “we do not believe that the diagnosis between induration and acute hydrocephalus is so difficult as writers pretend; not that it is so easy to recognise the former malady, but because, with a little attention, we can easily exclude the possibility of the meningitic disorder.” (See Rilliet.) *Partial induration* has been described by one or two continental writers, the symptoms of which are very obscure, chiefly consisting in very rapid emaciation, convulsions, and torpor.

By the *rapid atrophy* of the brain, treated of by Mauthner, you are in no danger of being misled: for here the patients continue living for a considerable time in a state of exhaustion, observing nothing, neglecting all usual amusements, “while the automatic movements of their limbs betray an intelligence not higher than brutes.” In that disease, which has been called *microcephalus* or congenital deficient develop-

ment of the brain, with a small skull, the very low state of the intellectual functions, will prevent a mistake. “Such children are on a level with ‘retins.’” Here the physical powers, however, are often very good.

Elasser and Widtmann have drawn our attention to a disorder which they respectively term *tetanus apnoicus* and *crania-tetanus*, and which they regard as a species of rachitism, exemplifying it in an atrophy of the cranial bones. This disorder is also accompanied with marks of inflammation of the meningeal membranes, and presents certain symptoms which might lead to the opinion that the child was suffering under tuberculous meningitis. From what I can glean from nine or ten cases of Widtmann (detailed in the *Gazette Medicale* for March, 1845), the following seem to be important signs of the disorder:—Great perspiration about the occipital region, which is soft and yielding to the touch; desire to lean the head forward, pressing on the brow, leaving the occiput free; great agitation in the night, especially if the child is not put to sleep lying on its side; great tendency to *laryngismus stridulus*; tonic and clonic spasms, or periodic tetanic disturbance of variable intensity; discharges more frequent between the third and sixth month after birth. In two out of nine cases the child died; in one only the state of the brain and membranes noticed, and this is said to have been normal. The laryngitic symptom is said to be owing to temporary congestion of the brain, become more sensible by the thinning of the cranium. The above may help your diagnosis, should such a case come before you.

In those cases of *phlebitis of the sinuses of the dura mater* which have been recorded, and in which the patients died after presenting cerebral symptoms, such as giddiness, syncope, dilatation of the pupils, strabismus, grinding of the teeth, alternate contraction and relaxation of muscles, &c., secondary affections have given rise to these symptoms, such as hemorrhage, effusion of fluid in the ventricles, softening, capillary apoplexy; or these lesions have existed, and yet the symptoms were such that no connection could be traced between them. In some examples death has been quite sudden.

With respect to the diagnosis between “acute hydrocephalus” and febrile diseases, I may remark that *typhoid fever* is not very frequent in children; the tongue is brown and loaded, diarrhoea often present, and heat of body and thirst in the early periods more intense; the pulse is more equable, as is also the respiration; there is much more debility from the onset, and an absence of convulsions, paralysis, &c., and other peculiar cerebral symptoms usually seen in the affection of the brain.

Remittent fever is more common, abdominal complication frequent and evident, and the lips red, chapped or fissured, and retracted in bad cases. In the milder, the regular remissions and exacerbations of the fever, the heat, the thirst, the readily-procured evacuations, the often brightness of the eye, and the state of the tongue, together with, in many cases, the ex-

istence of stomatitis, will help the diagnosis. In the brain disorder, the abdominal or digestive complications are attended with well known cerebral symptoms and tense fontanelles, and the lips, tongue, heat of body, thirst, and appearance of the eyes, are not those of the febrile disorder.

Now and then, even with your greatest attention, however, you will find yourselves at a loss to diagnose between certain forms of remittent fever and particular stages of tuberculous meningitis. I have now and then been at loss to say whether the head symptoms which were present, together with much heat of skin, febrile exacerbation, and derangement of the digestive system, were really secondary to the febrile disturbance, and were to be viewed as likely to yield as the fever subsided, and that they were only evidences of temporary irritation of the nervous centre. In such cases I have always acted, however, very carefully, as I know that this temporary cerebral irritation and congestion of the nervous centre, not uncommon in the remittent fever of childhood, may in a scrofulous child lead on to perfect development of an intercurrent form of the true meningitic disorder. Upon this point, however, I shall treat more fully when I speak to you of the fever in question.

Now and then you may be called to a case on account of the fears entertained from brain symptoms present, even accompanied with convulsions. Perhaps the next day you will find that they have entirely subsided, and that the little patient is covered with one of the exanthematous eruptions. But a fortnight ago I was called to a case of this description, and on my second visit found the infant covered with a dark mealy eruption; the child laboured, in fact, under that disorder which is called *rubeola sine catarrho*. But in these cases—at least those which I have seen—of the exanthemata being ushered in by head symptoms, there has not been the constipation which is observed in the meningitic disorder, nor in the younger children the tense fontanelles. In *smallpox*, which you meet with amongst the children of dispensary practice, you will often find vomiting and head symptoms usher in the malady, and it is in this exanthematous disorder that you will have to be most upon your guard in your diagnosis. I think you can better tell what is coming in *scarlatina* than in the other eruptive fevers, for here is from the first a peculiar state of the tongue and dryness of the mouth, with a strange sort of odour of the breath, even from the very first, that are not so likely to mislead you. In *measles*, too, you will, of course, mostly have the affection of the mucous membrane of the eyes and nasal passage, &c., to guide you; but, as in the case I have just told you of, they may all be wanting. In this the eruption receded very soon, but the infant was considered to be going on so well that my attendance was no longer required; but I heard from the family attendant that four or five days afterwards it died suddenly in convulsions.

The cerebral irritation which often intercurrents during difficult dentition may simulate somewhat the premonitory symptoms of tuberculous meningitis. But in these cases the swollen, tender, hot, and redder gums, and the very great dryness of, or, on the contrary, the continuous dribbling from the mouth, the more irritable disposition, the frequent precession or coexistent existence of diarrhoea, will assist you in your diagnosis.

The presence of worms sometimes induces anomalous nervous symptoms, about which I may just caution you, so that you may be upon your guard, as also the forcing little children to too early and long-continued mental exertions, at some of our new-fashioned schools.

You know that in the scrofulous child severe internal otitis and purulent otorrhoea are not unfrequent affections. In bad cases involvement of the temporal bone is seen to take place, and you can readily imagine that, if this proceeds to any extent, it will be likely to affect the contents of the cavity which it surrounds. And so it does sometimes, the brain and its membranes

becoming secondarily affected. Sometimes the discharge ceases suddenly, and is accompanied by a sort of internal throbbing, stupor, convulsions, or slight delirium, or with partial paralysis. The brain disorder may suddenly supervene, and death quickly follow, and on dissection after death evidences of simple secondary meningitis or cerebritis be present. On the other hand, the brain affection may take place more slowly, and assume the characters of common tuberculous meningitis. Dr. Cheyne, in his "Essays on Hydrocephalus Acutus," quotes several instances of secondary brain affection from disease of the ear. More lately, Dr. Cormack has called attention to the intimate connection between abscess of the brain and affections generally of scrofulous origin commencing in one of the structures of the internal ear; and you will find a notice of a very interesting case of abscess of the brain in a young female labouring under disease of the ear, which occurred to Mr. Hancock, in No. 341 of the *Medical Times*; I chiefly notice these cases in order to show you that the brain symptoms which may thus supervene are not to be regarded as those of idiopathic or primary disorder of the nervous centre, and treated accordingly.

I shall conclude what I have to say on the diagnosis of the disease I have been considering, in making a few remarks upon what Dr. Elliotson has called "spurious hydrocephalus," and to which other names have been given by various writers. You must know that sometimes soon after a naturally weak or badly brought up child has laboured under diarrhoea, or some exhausting disorder, or at a more late period of like affections in a stronger one, there will occur brain symptoms very apt to mislead an incautious practitioner into a belief that they indicate the supervention of our present disorder, or are to be viewed as symptoms of common hydrocephalus: the truth being that they are the evidences of vital exhaustion, and a very depressed condition of nervous energy—a state to be treated in a different manner from its first appearance to that which you must have recourse to in the other affection.

When I have seen this peculiar condition I have generally observed it in the stage alluded to by Dr. Gooch—viz., the child lying on the nurse's lap, unable or unwilling to raise its head; half asleep, one moment opening its eyes, and the next closing them again with a remarkable expression of languor; there is great heaviness of head, drowsiness, but no pain or active febrile symptoms present. In addition to these symptoms, and on which I lay great stress, are the great pallor of the face and coldness of it, as well as of the extremities. These symptoms may be followed by "coma, stertorous breathing, and dilated and motionless pupil," or even squinting and blindness—(Maunsell and Evanston).

Dr. Marshall Hall, to whom we were first indebted for having our attention prominently directed to this affection, divides it into two stages: the first being that of irritability, the second that of torpor. In the first "the infant becomes irritable, restless, and feverish, the face flushed, the surface hot, and the pulse frequent; there is an undue sensitiveness of the nerves of feeling, and the little patient starts on becoming touched, or from any sudden noise; there are sighing and moaning during the sleep, and screaming; the bowels are flatulent and loose, and the evacuations are mucous and disordered." Now, if these symptoms are not properly treated by the administration of gentle stimulants and cordials, the second stage of Dr. Hall will follow, and the patient sink in a state of collapse. The second stage, with which I am alone familiar, is marked by the symptoms I have just spoken of. However, I cannot do better than refer you to the last edition of Underwood, in which you will find much more about the disorder.

If you were called to a case where the child is lying, as I said, on the nurse's lap,—either very drowsy, or in a state of great languor, or in deep stupor (for I do not know what else to call it), with pale cold face and extremities, dim eyes, perhaps squinting or dilated pupil, or with, now and then, twitchings, or even convulsions, and

irregular or suppressed respiration,—you should at once inquire if the child has had diarrhoea for sometime, or has been treated by much depletion in any way for a presumed inflammatory disorder: for, if such has been the case, it is in all likelihood suffering under intense depression of vital power, and it must be treated accordingly. It is in this, also, that I agree with Gooch, in only having seen this "spurious hydrocephalus" occurring after exhaustion from diarrhoea and depletory treatment; and this is a very great point for me to help myself in the diagnosis. On the other hand, Dr. Hall, in most of the cases he has seen, says that "the child has had no previous illness, and the leeches have been applied subsequent to the drowsiness, and as a remedy for it." But still Dr. Hall admits that a state of exhaustion had existed previously in all the cases he had seen or heard of.

A peculiar condition of the brain has been spoken of by Dr. Nickoll, which he calls *erethism*, and of which he makes two varieties, *sensitive* and *torpid*.

Out of his sensitive *erethism* I can make nothing but *congestion*, and the torpid appears to me to be a variety of the disorder we are at present speaking of; but still one with which I am not personally acquainted. My own experience does not allow me to say that I am aware of a hydrocephaloid affection, save as following upon exhausting disease or a like cause, but others assert that it does. Of course I am aware that general constitutional debility will give rise to anomalous nervous symptoms, but I never saw it produce anything like "spurious hydrocephalus," such as I have been talking of, unless combined with, or immediately preceded by diarrhoea or loss of the circulating fluid. Still, the following observations of Dr. Henry Davis are worthy of your attention:—"Although exhausting discharges are for the most part the more frequent cause of hydrocephaloid affection, yet the disease sometimes takes place without any apparent cause of exhaustion; and alterations in the quality of the blood, or in the nutrition of the brain, sometimes induce the same train of symptoms. Hence defective nutrition of the body, and an imperfect supply of other vital stimuli, particularly air and light, may, by first inducing a state of irritation, eventually induce congestion or the symptoms simulating hydrocephalus; and, in accordance with Dr. Bennet's statement, it is in the feeble children of the poor that hydrocephaloid affections are more commonly seen, except in those cases where they follow direct exhaustion."

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART VI.

RESPIRATION—ENDOSMOSIS OF GASES.

The action of the atmospheric oxygen upon the venous blood, the changes which the inhaled air suffers in the pulmonary cells, the modifications which the blood undergoes in the capillary network spread over the thin partitions of the bronchial vesicles—these are the principal phenomena that constitute the function of respiration.

The life of all animals, without exception, is essentially dependent upon the modifications which the atmospheric oxygen operates in their substance. The organs charged with the respiratory function, in the divers classes of animals, are more or less developed, and of different form and organization, according to the nature of the medium in which the several classes respectively exist. These differences are so well known that we need not here expatiate upon them.

The mechanism of the respiratory movements may be aptly illustrated by the action of a bellows.

Man introduces into his lungs, in every in-

halation, about one-third of a litre (a) (about one half-pint) of atmospheric air; the exhaled air contains from 3 to 5 per cent. of carbonic acid, and in very full and deep exhalations as much as from 6 to 8 per cent.; on the other hand, the exhaled air contains from 4 to 6 per cent. of oxygen less than it contained at its inhalation. With these data (which have been selected from among a great number, as the most trustworthy) we can readily calculate the quantity of oxygen absorbed by an individual in the space of twenty-four hours, assuming the number of inspirations per minute to vary between 15 and 20. According to Lavoisier and Séguin, the oxygen consumed by the respiration of an adult amounts to 1015 grammes per diem. The volume of oxygen which disappears in the respiration of man and of birds is nearly equal to that of the carbonic acid eliminated. Very scrupulous observers have found that the volume of oxygen absorbed in respiration is more considerable than that of the carbonic acid produced in this process. This difference is more particularly marked in the carnivora: Dulong found in the course of his experiments that, in this class of animals, the amount of oxygen absorbed is sometimes double that of the carbonic acid formed.

Dulong and Despretz have proved beyond question that the exhaled air contains a larger proportion of nitrogen than the atmosphere. This excess of nitrogen is furnished by the food, and may, perhaps, also proceed from the nitrogen which we presume to exist in the stomach and intestines, as residue of the air that has been introduced into these viscera with the food. It might be objected to this, that the proportion of nitrogen in the atmosphere remains invariably the same; but this objection is removed by Bousisingault's observation, that some plants absorb nitrogen.

The air dissolved in the water suffers the same changes in the respiratory process of the fishes. Common water and sea water hold a certain quantity of atmospheric air in solution, which may be disengaged by ebullition, or by bringing the water into contact with other gases, or may be withdrawn by means of the air-pump.

The experiments of Morren have shown that common water and sea water hold likewise a certain amount of carbonic acid in solution, which amount seems to vary in an inverse ratio to that of the oxygen present at the same time. The proportion of oxygen found in a certain definite volume of air dissolved in the water exceeds that in which this gas is found in the atmosphere. Humboldt and Gay-Lussac found 32 per cent. of oxygen in the air withdrawn from spring water. According to Morren, the proportion of oxygen present in the air in sea water seems to vary in the different hours of the day—attaining its maximum at noon; the proportion of carbonic acid seems to vary in the inverse sense. Fishes absorb a portion of this dissolved oxygen, and yield, in return carbonic acid, which is absorbed by the water. The respiration of these animals, therefore, can be maintained only by the constant solution of fresh particles of atmospheric air in the water. Fishes die speedily in water covered with a layer of oil, and in water from which the air has been expelled by ebullition. A large torpedo was kept for forty-five minutes in about one gallon of water of the Adriatic, taken near the coast; the air in this water was found to be composed of,

10 of carbonic acid.
60.5 of nitrogen,
29.5 of oxygen.

The torpedo was frequently excited, and gave accordingly a great many shocks, and died speedily. The air in the water was, upon analysis, found to contain thirty-six per cent. of carbonic acid, and sixty-four per cent. of nitrogen; every trace of the oxygen had consequently disappeared.

Experience has proved that these changes in the composition of the air are not effected

by the lungs alone, but that the whole surface of the animal body produces similar modifications, though in a different degree. Frogs deprived of their lungs, or prevented in some other manner from breathing, continue to live; and, when placed in that state in a certain definite amount of air, it will be found after some time, that a portion of the oxygen has disappeared, and is replaced by carbonic acid. Humboldt and Provençal saw tenches live without great sufferings, although their head and gills were kept above water. Spallanzani and Edwards have proved, moreover, that frogs could not exist without cutaneous respiration. It has been observed that frogs deprived of their lungs exist for several days, whilst, on the contrary, the removal or varnishing of the skin kills them in the space of a few hours. Sorg kept one of his arms immersed for four hours in oxygen gas; he found, after the lapse of that time, that about two-thirds of the gas had disappeared. Davy injected air into one of the pleura of a dog: upon analyzing the injected air, a short time after, he found only slight traces of oxygen left in it.

That the venous blood is changed in the lungs during the act of respiration into arterial, and its dark colour to a fine vermilion, and that the interruption of this transmutation of the blood causes speedily death, are facts universally known.

The inspiration of nitrogen gas, pure or carburetted, or sulphuretted hydrogen, carbonic oxide, carbonic acid, or binoxide of nitrogen (nitrous gas), is more or less speedily followed by death; the blood, in such cases, is found black throughout the body. With oxygen and protoxide of nitrogen, respiration may be maintained for a short time—indeed, with oxygen this function might be maintained much longer, were it not that the inspiration of that gas augments and accelerates the respiratory movements and arterial pulsations to an extent incompatible with the continued normal performance of the respiratory and circulatory functions. Protoxide of nitrogen likewise accelerates the respiratory movements; the cerebral functions become disturbed, and a kind of intoxication supervenes.

Having thus briefly discussed the phenomena of respiration, we are naturally led to the question: are these phenomena effected exclusively and alone in living bodies?—or do changes analogous to those observed in the act of respiration continue for some time to take place between venous blood removed from the living organism, and the oxygen of the atmosphere? These questions have long been solved by actual experiments, and the purely physico-chemical nature of the respiratory phenomena (modifications of the blood and of the inhaled air) has been proved beyond controversy.

But what is the nature of the change which the venous blood suffers by the action of the atmospheric oxygen? What are the laws that preside over this change? In our endeavours to solve these questions we must have recourse to the fine researches of Magnus.

If blood drawn from a vein of an animal be caught in a receiver containing pure hydrogen gas, and agitated with this, a certain amount of carbonic acid will be found in the receiver, which certainly cannot proceed from any chemical combination of the hydrogen with the elements of the blood, nor can we imagine it to have been expelled from the blood by the affinity of the hydrogen for the body with which the carbonic acid might be supposed in combination in that fluid. It is, therefore, evident that the blood contains carbonic acid in solution, and that the disengagement of this gas by the hydrogen is simply owing to the action which one gas exercises upon another gas of a different nature dissolved in a liquid. If the same operation be performed with arterial blood, the quantity of carbonic acid obtained will be found less than in the case of venous blood. The same results will be obtained if nitrogen be substituted for the hydrogen—the quantity of carbonic acid obtained from venous blood being double that obtained

from arterial blood. The application of this method disengages not only the carbonic acid, but also the oxygen and nitrogen, which the blood holds in solution. The following table shows the numeric results (in cubic centimetres) obtained by Magnus in his experiments upon this subject, relative to the respective amount of the gases which the blood holds in solution:—(Magnus operated with a particular apparatus which enabled him to create a vacuum above the blood.)

Arterial blood of a horse, 125 CC, yielded . . .	9.8 of gas	5.4 of carbonic acid, 1.9 of oxygen, 2.5 of nitrogen.
Venous blood of a horse, 205 CC, yielded . . .	12.2 of gas	8.8 of carbonic acid, 2.3 of oxygen, 1.1 of nitrogen.
Arterial blood of a horse, 130 CC, yielded . . .	16.3 of gas	10.7 of carbonic acid, 4.1 of oxygen, 1.6 of nitrogen.
Venous blood of a horse, 170 CC, yielded . . .	18.9 of gas	12.4 of carbonic acid, 2.6 of oxygen, 4.0 of nitrogen.
Arterial blood of a calf, 123 CC, yielded . . .	14.5 of gas	9.4 of carbonic acid, 3.5 of oxygen, 1.6 of nitrogen.
Arterial blood of a calf, 108 CC, yielded . . .	12.6 of gas	7.0 of carbonic acid, 3.0 of oxygen, 2.6 of nitrogen.
Venous blood of a calf, 253 CC, yielded . . .	13.5 of gas	10.2 of carbonic acid, 1.8 of oxygen, 1.5 of nitrogen.
Venous blood of a calf, 140 CC, yielded . . .	7.7 of gas	6.1 of carbonic acid, 1.0 of oxygen, 0.6 of nitrogen.

Taking the average of these numbers, and, calculating them upon 100 parts of blood, we find that

100 CC of arterial blood contain . . .	10.4276 of gas	6.4967 of carbonic acid, 2.4178 of oxygen, 1.5131 of nitrogen.
100 CC of venous blood contain . . .	7.6825 of gas	5.5041 of carbonic acid, 1.1703 of oxygen, 1.0081 of nitrogen.

It would be highly desirable that these experiments of Magnus should be repeated and extended still further, more especially with a view to arrive at the absolute quantities of the several gases which the blood holds in solution.

The following conclusions drawn from the results of Magnus's experiments are, however, even as the matter stands at present, of the highest interest for the theory of respiration:—

1. The arterial blood contains a larger amount of gas than the venous blood.

2. The amount of oxygen found in arterial blood is double that found in venous blood.

3. The proportion of the oxygen to the carbonic acid is, in arterial blood = 1 : 3, and nearly like 1 : 2; whilst in venous blood it is only like 1 : 4, and even as little as 1 : 5.

The transformation of the venous into arterial blood is effected in the lungs where the atmospheric air and the blood are brought into almost immediate contact with each other, being separated only by an exceedingly thin membrane. It is essential now to prove that the reciprocal action of the gases, and the change of colour which the blood suffers in the act of respiration, take place likewise, and in the same manner, through the layers of membranes, without the slightest possible intervention of the vital force, or, in other words, out of the living organism.

Gases enclosed in bladders escape speedily through the pores of the latter, and are replaced by atmospheric air. Were the volume of the latter not so infinite as compared to that of the gas within the bladder, the exchange between the two would be suspended after a certain time, and both within the bladder and without would be found a mixture of the two. Place a bladder, filled with water slightly acidulated with carbonic acid, under a glass jar filled with hydrogen, oxygen, or nitrogen, and, after the lapse of some time, you will find that a portion of the carbonic acid has escaped from the water in the bladder, and that a portion of the gas originally in the jar has penetrated through the bladder and is now held in solution by the water.

(a) One litre is about 50½ cubic inches Par.; the English quart about 66½ Par. cubic inches.

Generally speaking, two gases, separated by a membrane, and of which the one is free or dissolved in a liquid, exert a reciprocal action upon one another, and intermix in definite proportions.

It would be highly desirable that a series of experiments should be made, with a view to determine the laws of this phenomenon, regard being had to the respective nature and density of the gases, and to the nature of the interposed membranes. The result of some such experiments, made by the author, would lead to the assumption of a phenomenon analogous to that of endosmosis in this interchange and intermixture of gases. The author took the lungs of a recently-killed lamb, withdrew the air from them by suction as carefully and completely as possible, filled them partially with oxygen gas, tied the trachea tightly, and placed the lungs thus prepared under a jar filled with carbonic acid and inverted over water; after the lapse of a short time, the lungs were seen to swell and distend as far as the capacity of the jar would permit. The gas was analyzed after the experiment, and it was found that a portion of the carbonic acid had penetrated into the pulmonary cells, and that oxygen had been disengaged from them, but not in equal volumes—the amount of the carbonic acid introduced into the pulmonary cells exceeding that of the oxygen disengaged from them. In one experiment of this kind, which was continued for four hours, the author found the mixture in the lungs to consist of two-thirds of oxygen and one-third of carbonic acid, and the mixture in the jar of one-fourth of oxygen and three-fourths of carbonic acid.

Soap bubbles filled with atmospheric air, or with hydrogen gas, and dropped into carbonic acid, increase in bulk; and it is a curious fact that, notwithstanding their dilatation, they sink to the bottom of the jar containing the carbonic acid. The excess of carbonic acid that penetrates into the bubble causes the latter to increase in bulk on the one, and in weight on the other hand—balancing thus the relative loss of weight attendant upon the increase of volume; at the same time the layer of water forming the envelope of the bubble dissolves a portion of the carbonic acid, and thus again increases the weight of the bubble.

The author filled a bladder with oxygen, and placed it subsequently into carbonic acid, taking care to keep the bladder perfectly dry; the bladder did not distend; after the lapse of some time, however, it was found that the interchange between the two gases had taken place, but in equal volumes. In another experiment, the author filled a lung with carbonic acid as completely as he could effect, and placed it subsequently into oxygen; the result was collapse of the lung and intermixture of the two gases, but the amount of carbonic acid that escaped from the lung was more considerable than the proportion of oxygen that entered it. Thus it seems evident that, in all these cases, we are to take into account—besides the reciprocal action of the two gases separated by the membrane—the water bathing the latter, since this dissolves a certain amount of carbonic acid; the acid liquid, thus formed, finds itself on one side in presence of a gas different from that which it holds in solution, and which acts upon the latter as it would *in vacuo*. We might, accordingly, account for the excess of carbonic acid introduced into the soap bubble and lungs, by attributing it either to a species of gaseous endosmosis, or to the solution and subsequent exhalation of this gas. To elucidate this question, experiments should be made with gases that have no affinity for water. The laws discovered by Graham, regarding the diffusion of gases in the air, bear also upon this subject. Graham has established that the power of diffusor of gases in the air, when separated from the latter by a membrane or a layer of mortar, is proportional to the square roots of their respective densities. The recent researches of Valentin and of Brunner tend to show that the same law holds good in the phenomenon of respiration.

Spallanzani, Nysten, Martigny, Edwards, et

celled the air from the lungs of frogs, by pressure upon the chest and abdomen of the animal; this operation was, of course, performed with the greatest care and caution, as are all the experiments made by these scrupulous observers. The lungs thus voided, some of the animals were placed in hydrogen, others in nitrogen gas. Dogs, rabbits, and a number of other animals were subjected to the same process, either with voided lungs, or lungs filled with artificial air. The results were invariably the same: the hydrogen or nitrogen gas was absorbed, and carbonic acid exhaled in its place; and, besides this, nitrogen, in all cases where the animals had been placed in hydrogen. A mixture of oxygen and nitrogen, containing the former element in larger proportions than it exists in the atmosphere, was introduced into lungs, previously voided, by means of a syringe. The amount of carbonic acid inhaled was found to be proportionally larger than is the case in the respiration of atmospheric air. Frogs emit carbonic acid in hydrogen and in nitrogen, even though deprived of their lungs.

These facts, taken collectively, lead to the following conclusions:—

1. That the respiratory function is a purely physico-chemical phenomenon.
2. That the gases which the venous blood holds in solution are liberated by the absorption of other gases.
3. That a portion of the carbonic acid of the venous blood is exhaled by the absorption of the atmospheric oxygen operated by this fluid.
4. That the carbonic acid exhaled, or, at all events, the greater portion of it, is not formed in the lungs, but exists in solution in the venous blood, and is liberated during the act of respiration, by the agency of the oxygen introduced in its stead, in the same manner as it is liberated by the agency of the nitrogen or hydrogen in the artificial respiration of the latter gases.
5. That it results from Magnus's experiments, that the five pounds of blood passing through the lungs every minute hold an amount of carbonic acid in solution nearly the double of that which is exhaled in the same period of time.

DUMAS ON ORGANIC CHEMISTRY.

No. XXV.

(Continued from page 369.)

ON THE MILK—(continued).

MM. Boussingault and Le Bel have, in their turn, made some experiments upon the milk of the cow; and they appear to have drawn a conclusion, that the nature of the aliments consumed does not exercise any very marked influence upon the quantity and chemical constitution of the milk, provided care be taken to give to the animals equivalent nutritive quantities of the different kinds of food. The following table presents the result of their experiments:—

Composition of the Milk.

No. of cows since parturition	Time in hours	Food consumed in 100 parts of milk	Aliments received, equivalent to fifteen kilogrammes of hay.	Sugar in milk	
1	5.0	21.6	Potatoes, hay	15.1	2.6 3.6 0.3 78.4
13	7.5		Do.		
24	10.6		Hay, green trefoil	3.0	3.5 4.5 0.2 88.8
36	12.0		Green trefoil	3.1	5.6 4.2 0.3 86.9
200	5.6		Hay	3.0	4.5 4.7 0.1 87.7
207	6.0		Turnips	3.0	4.2 5.0 0.2 87.6
215	5.6		Beetroot	3.4	4.0 5.3 0.2 87.1
229	5.0		Potatoes	3.4	4.0 5.9 0.2 86.6
240	3.6		Hay		
270	3.4		Potatoes		
290	3.5		Artichokes	3.3	3.5 5.5 0.2 87.5
302	2.8		Hay and oil-cakes.	3.4	3.6 6.0 0.2 86.8
			Influence of green food.		
176	9.3		Potatoes, hay	3.3	4.8 5.1 0.3 86.3
182	8.9		Hay, green trefoil	4.0	4.5 4.0 0.3 87.2
193	9.8		Green trefoil	4.0	2.2 4.7 0.3 88.8
204	7.8		Trefoil in flower	3.7	3.5 5.2 0.2 87.4

Now, do the above aliments contain the principles which are found in the milk? There is no doubt but that the saline matters, which exist in this liquid, are carried directly to it by the drinks and by the food. As to the sugar of milk, it may arise from the saccharine, amylaceous, or gummy matters, which enter so largely into the food of the herbivora. We have seen that, under the influence of a purely animal regimen, the lactose disappears, or, at least, it is produced in a perfectly inappreciable quantity. The origin of the caseine is equally apparent: this principle results from the transformation of the albuminous matters contained in the aliments, and which are capable of undergoing so many and such ready isomeric modifications.

It is not so easy to state the source of the butter contained in the milk: for, if it is evident that the various fatty matters belonging to the aliments invariably concur in a direct manner to the formation of butter, it is also certain, according to the recent experiments of M. Boussingault, that the influence of the aliments is not confined to this limited action; but that, by a principle analogous probably to that which we observe in fermentations, they determine a more abundant formation of the fatty matter at the expense of some of the bodies which they contain. M. Boussingault thinks that the fatty principles naturally contained in the aliments exercise over the production of the butter a double influence, not only by concurring themselves to its formation, but also by favouring those metamorphoses, in consequence of which the saccharine, gummy, or amylaceous matters are capable of being partially transformed into fat.

The diet is not the only circumstance capable of influencing the production of the milk. Hygienic conditions, age, race, &c., may exercise over the same species of animal a very marked effect as regards the abundance and quality of this secretion. For agricultural purposes, sound animals, or such as are of good breed, are always preferable, although in some cases it may be difficult to foretell what individuals will furnish the best milk, under the same conditions of food, &c.

The moral agencies have a very marked influence upon the secretion of milk: fright, excess of joy or anger, may interfere very injuriously with, and in some cases altogether check this secretion. It is especially with women that these causes have the greatest influence, in whom the milk will, under such circumstances, sometimes become positively injurious to the young one. Examples of this kind may be found in animals, but here they are much more rare.

The quantity of milk in the cow, setting out from the period of parturition, may be said to augment for the first month or six weeks; after which it gradually diminishes. We have merely to glance over the table given by M. Boussingault

to be convinced of this fact. Neither the season of calving, nor the quality of the food, provided always that it remain equivalent to fifteen kilograms of hay, in any way modify the abundance of the secretion.

The chemical constitution of the milk ranges within very narrow limits; in fact, in the table already mentioned, we find that it invariably contains close upon twelve or thirteen per cent. of solid matters. The caseum varies but slightly, although we may perceive that, after the secretion

of the colostrum has ceased, this principle presents a trifling augmentation. The butter offers marked variations; as to the sugar, it appears to augment with great regularity, in proportion as we recede from the period of parturition.

M. F. Simon has arrived at analogous results by analyzing the milk of the human female; only, in the latter, the sugar diminishes the further we advance from the time of childbirth.

The following table gives the result of his analyses:—

DATE.	Density.	Water.	Solid residue.	Caseum.	Sugar.	Butter.	Salts.
August 31	1.0316	873.2	126.8	21.2	62.4	34.6	1.92
September 7	1.0300	883.8	116.2	19.6	67.6	31.4	1.66
" 8	1.0300	899.0	101.0	25.7	62.3	18.0	2.00
" 14	1.0300	883.6	116.4	22.0	62.0	26.4	1.78
October 27	1.0340	898.2	101.8	43.0	45.0	14.0	2.74
November 3	1.0320	886.0	114.0	45.2	39.2	27.4	2.87
" 11	1.0345	914.0	86.0	35.3	39.5	8.0	2.40
" 18	1.0330	880.6	119.4	37.0	45.4	34.0	2.50
" 25	1.0334	890.4	109.6	38.5	47.5	19.0	2.70
December 1	1.0320	902.0	98.0	39.0	49.0	8.0	2.08
" 8	1.0330	890.0	110.0	41.0	43.0	22.0	2.76
" 16	1.0344	891.0	109.0	42.0	44.0	20.0	2.68
" 31	1.0340	861.4	138.6	31.0	52.0	54.0	2.35
January 4	1.0320	873.6	126.4	40.0	46.0	37.0	2.70

M. Peligot directs attention to the influence which weaning exercises over the qualities of the milk; he concludes, from his experiments, that the milk becomes proportionally poorer, as the interval since the last draught is more lengthened. Annexed are some analyses, which he made on this subject, upon the milk of the ass:—

	One hour and a half after suckling.	Six hours after.	Twenty-four hours after.
Butter ..	1.55	1.42	1.23
Sugar of milk ..	6.65	6.40	6.33
Caseum ..	3.46	1.55	1.01
Solid matters ..	11.66	9.37	8.57
Water ..	88.34	90.63	91.43
	100.00	100.00	100.00
	Six hours after suckling.	Twelve hours after suckling.	
Butter ..	1.73	1.51	
Sugar of milk ..	7.00	6.70	
Caseum ..	1.25	1.10	
Solid matters ..	9.98	9.31	
Water ..	90.02	90.69	
	100.00	100.00	

Not only will the milk differ in its composition according to the length of time elapsed since the last suckling, but also it may present, on analysis, sensible variations, according as it has been taken at the commencement or towards the end of the draught. Thus, after remaining nine hours without suckling, the milk of the ass yielded by analysis the following results, on dividing the fluid drawn into three portions:—

	I.	II.	III.
Butter ..	0.96	1.02	1.54
Sugar of milk ..	6.50	6.48	6.45
Caseum ..	1.76	1.95	2.95
Solid matters ..	9.22	9.45	10.94
Water ..	90.78	90.55	89.06
	100.00	100.00	100.00

Parmentier and Deyeux have likewise arrived at similar results, by analyzing the cream taken from different portions of milk. It is, as we see, chiefly in the butter and the caseum that these variations are found.

M. Quévenne has confirmed this result, by determining the volume of the cream, the density of pure milk, and that of the same fluid when skimmed. The following are the results of his experiments.

Acid milk taken eleven months after parturition:—

	Density of the milk.	Density of milk skimmed.	Cream obtained in 4 hours.
Commencement of the draught ..	1.0326	1.0352	5
Middle of ditto ..	1.0316	1.0362	6
End of ditto ..	1.0296	1.0342	12

Alkaline milk taken ten months after parturition:—

	Density of the milk.	Density of milk skimmed.	Cream obtained in 4 hours.
Commencement of the draught ..	1.0299	1.0322	
Middle of ditto ..	1.0297	1.0347	15
End of ditto ..	1.0274	1.0337	21

We shall presently find, that the composition of the milk may change according as it is taken from a healthy or from a diseased teat.

Many chemists have employed themselves in analyzing the milk; of these some have adopted different methods. M. Berzélius analyzed separately the cream and the skimmed milk; this plan has, however, been abandoned. M. Peligot employs a very simple process, and one which seems to give pretty accurate results; it consists in evaporating, in a water-bath, a certain quantity of milk, the density and volume of which have been previously determined. When the residue ceases to undergo any further reduction, it is to be carefully weighed; we then treat it by a mixture of alcohol and ether, which removes all the fatty matter. The next step consists in drying the residue, and once more weighing it, when the difference of the two weights gives the amount of butter. By washing in cold water, the caseum is left behind, whereas the saccharine matter and the soluble salts are removed, and may be subsequently separated by means of alcohol, which menstruum does not dissolve the sugar of milk.

This process presents one inconvenience: a little caseum is invariably taken up by the cold water; this amount appears to be greater with the milk of the human female than with that of the cow. We cannot, therefore, affirm that this proceeding gives exact results; nevertheless, it has rendered considerable service; and, if it has at the present day been nearly abandoned, this is chiefly on account of the slowness and difficulty experienced in evaporating the milk to dryness, and also because the caseum becomes somewhat altered and partially soluble.

M. Simon desiccates the milk, weighs the residue, pulverizes it, and treats a fixed quantity, at three separate intervals, with five or six times its volume of sulphuric ether: this isolates the fatty matter. He then digests, for a certain time, the residue, freed from fat, in a little hot water. The substance thus obtained is after-

wards thrown into a large quantity of water. If operating on the milk of the cow, this becomes in chief part dissolved; whereas a considerable residue of insoluble caseine remains from the milk of the human female. The solution is now evaporated to a syrupy consistence, taking care properly to regulate the temperature, and then the whole is treated by ten or twelve times its volume of alcohol at 0° 85°. The caseine becomes precipitated; but, as it still retains some sugar, it is advisable to wash it in water and in alcohol. Lastly, he dries it thoroughly and weighs it.

The alcoholic solutions carry off the sugar and the greater part of the extractive matters, which it becomes very difficult to separate. We may, however, succeed in this, by dissolving the impure sugar in a small quantity of water, and then precipitating it by pure alcohol. The alcohol retains the extractive matters and a little sugar. This treatment may be repeated so as to effect a more complete separation of these principles. The amount of the salts may be ascertained by incinerating a portion of the desiccated milk.

When the milk contains albumen, we determine its quantity by a separate mode of treatment; that is to say, by coagulating it by heat, then washing the precipitate in dilute alcohol, and subsequently in ether.

M. Quévenne analyzed the milk by precipitating the caseum by acetic acid, and washing the precipitate in pure water; after drying it, he treated it by a mixture of alcohol and ether. The serum is then evaporated to dryness. This process may be effected with rapidity, but it is apt to be incorrect in its results.

M. Lecanu prefers the coagulation of the milk by dilute alcohol. He thus separates the caseum, which he frees of all fatty matter by means of ether. The evaporated liquor furnishes the sugar of milk and salts, which are to be separated by means of cold water and pure alcohol.

M. Haidlen has, more recently, reduced the milk, by coagulating it by means of sulphate of lime. For this purpose, we are to pour the milk into a clean glass vessel, containing about one-fifth part of hydrated sulphate of lime, previously dried at a temperature of 100° C.; by applying a gentle heat, the milk becomes coagulated. On evaporating it to dryness in a water-bath, we obtain a mass readily reducible to a fine powder, which is to be acted on successively by ether and by alcohol; the ether removes from it the butter, and the alcohol dissolves the sugar and soluble salts, without touching the caseine which is perfectly coagulated. The residue contains a cascade of lime with an excess of gypsum. By deducting from the weight of this residue that of the sulphate of lime employed, we obtain the amount of caseine.

But we cannot make an exact analysis of the milk by any one of these processes. In evaporating the milk *en masse*, or the serum, by means of heat in the open air, the extractive matter becomes greatly altered. These operations should, therefore, be performed *in vacuo*. Moreover, to determine the amount of butter, it is better to boil the milk, having previously strongly acidulated it by means of acetic acid; then, to allow it to cool, and to agitate it twice or thrice with an equal volume of ether, which removes the butter. When we wish to ascertain the quantity of soluble caseum, we should saturate the milk by chloride of sodium, and subsequently filter it. The limpid liquor, being coagulated by acetic acid or by alcohol, will furnish the caseum. As to the salts and sugar of milk, they will be found in the serum, freed from its butter and caseum by the ordinary methods, and then evaporating it to dryness *in vacuo*. By this means, we obtain a perfectly colourless residue.

FRENCH MEDICAL APPOINTMENTS.—M. Foully, inspector-general of the Naval Board of Health, is appointed to take a part in the high commission of Medical Education.

M. Villeneuve has been recently appointed medical director of the Lunatic Asylum of Dijon, in the place of M. Dugast, who has resigned.

OBSERVATIONS ON THE USE OF MERCURY IN SOME FORMS OF PRIMARY AND SECONDARY SYPHILIS.

By HENRY SMITH, Esq.,
Late House-Surgeon to King's College Hospital.

In my papers lately published in the *Medical Times*, on the Action of Mercury in Inflammation, I made allusions now and then to its use in the various morbid affections caused by the poison of syphilis; but refrained from dwelling upon that point at any length, as I considered it might well be made the subject of some future and distinct inquiry. I have no intention, however, of going at all fully into the old and hackneyed subject of the use and abuses of mercury in syphilis; but merely wish to make a few remarks on some points connected with its administration in this disease, which are the result of the experience of no inconsiderable number of venereal cases, and of much thought and inquiry on the subject. When asked a short time ago, by an old and retired practitioner, whether we had any regular period of time for continuing mercury in syphilis; and, again, when in consultation on a case of secondary syphilis, attended with severe irritative fever, it was proposed to rub into the thighs immediately a quantity of mercurial ointment, I could not help thinking that, however much improvement has taken place in the employment of mercury, at the same time there are unscientific and erroneous notions respecting its use still clinging closely to the minds of some who have been educated in a particular doctrine, and have not had the time or inclination to inquire into the points of that doctrine, as to whether they may be acted upon or not.

Much discredit has, I believe, been brought upon this remedy in consequence of a neglect of those rules which science, reason, and experience suggest to us in the administration of mercury, and which must be attended to, should we expect to gain a safe and successful end.

There are many cases of primary and secondary syphilis, occurring in particular constitutions, which demand great care and judgment in their treatment. A man, who is broken down in health from various accidental causes, gets a venereal sore. He, perhaps, has been in the habit of taking little animal food, consumes a vast quantity of gin, and is exposed to all sorts of temperature, and in this condition gets inoculated with a dreadful poison; he is weak, pale and thin; he is feverish; his pulse is frequent and compressible; and the sore has an unhealthy appearance. This is a picture of many of the cases which are daily seen amongst the poor of London, and these are the cases amongst which we occasionally see the most deplorable ravages committed.

The principles of the treatment in such cases differ in this respect from those which should be adopted in cases where the infection is received into a sound constitution and healthy frame, namely, that whilst in the latter case we extirpate the poison, without depressing the powers of life, or doing any injury by the remedy we use, in the former we extirpate the poison, and at the same time should do our best, not only to keep up but to restore the strength of the system, and revive its already depressed energies.

Mercury undoubtedly is the remedy in either case; and the remedy which I believe most English surgeons consider it a point of conscience to give; but the manner in which it is given should differ; and additional remedies are required in such cases as I have mentioned.

If such a case presents itself, it would be well to proceed cautiously with the use of mercury; some preparatory measures being premised, such as a warm bath, if possible, and a free unloading of the bowels, and a suppression of febrile symptoms. If the system is by these measures brought into a less morbid state, we shall be able to cure the patient with less mercury, and I believe that

should be an object in the treatment. The mercury should be commenced in small doses, and conjoined with some tonic which will serve as a kind of antidote against the depressing influence of mercury alone; and no tonic will serve better this purpose than quinine: it will render the system more susceptible of the influence of mercury, and at the same time make it proof against the injuries which in such a state the remedy and disease may alike produce. The preparation of mercury which I believe to be the best, is either the mercury with chalk, or calomel. The former is mild, unirritating, and easy of control; the latter is powerful, and at the same time safe. The former, however, will be the best, as it is the mildest, and yet I believe every good may be obtained from it. My friend Mr. Haynes Walton, who has the opportunity of using a considerable quantity of mercury in venereal affections of the eye, at the Central London Ophthalmic Institution, never employs any other preparation than this, and he assures me it answers every purpose. From two grains and a half to three grains, made into a powder with one grain and a half of quinine and a quarter of opium, may be given twice a day; or, if calomel is employed, a less dose may be given—from two to four grains daily.

At the same time the patient should be allowed to take solid meat, and milk. If the system is not very rebellious to the action of mercury, we shall find that in a short time (three or four days, perhaps, or a week) it will become affected, and that too without any great disturbance, but fairly and easily: the foundation of the cure will thus be laid.

The poison of syphilis has against it, in the blood, a more powerful antagonist; and the struggle for the mastery, one over the other, will take place and be completed without injury to the system, in consequence of the support which the more powerful has joined with it.

It will not do to give mercury in large doses, in a routine way, and without other suitable measures, in such cases as these; but I believe it is done daily; and I believe that a great number of those deplorable cases of syphilitic disease which are now occasionally seen, are owing to a carelessness in its use, as well by the educated practitioner as by those unscrupulous and rapacious quacks who fix like vultures on their prey, and feed upon the diseased and decayed bodies of their unsuspecting victims.

It is likely, in some cases I have been speaking of, that mercury given in this careful manner will not do its duty; the system will not get affected, or a train of symptoms will arise which will not warrant us to continue in its use. If the patient becomes weaker, gets feverish, and the sore begins to spread to any extent, and the mouth is not affected, there must be something wrong. It would be well to suspend its use for a time, and endeavour to get the system into a more tractable state by remedies adapted to the occasion, and then carefully commence the employment of mercury again. But great care is necessary, in some of these cases, lest phagedenic ulceration should be brought about, as will happen in an injured constitution, on incautiously receiving mercury when not prepared for it. I have lately had under my observation a deplorable case of this kind, where, in a weak constitution, mercury was taken to a considerable amount, and rapid ulceration took place over various parts of the body, with the loss of nearly the whole penis.

There are cases of syphilis occurring in individuals of a naturally scrofulous habit, who are otherwise healthy; these demand as much caution in the use of mercury as those I have been treating of.

In the lower classes of life, gin and want of animal food; in the higher classes, a more refined dissipation, are powerful allies to the poison already imbibed. There are some, I believe, who would not dare to give mercury to a scrofulous patient labouring under syphilis; but I believe it may be employed without injury, if due care is taken; and this may be gained by com-

bining the mercury with quinine, in the same manner I have before mentioned; and, other auxiliary measures being used, a cure may be effected safely and speedily. I have lately had a good opportunity of testing this in the case of a gentleman of good health and regular habits, but of a scrofulous family. Great irritation and depression ensued upon the introduction of the venereal poison into the blood, so that he was obliged to keep his bed for some days. After some preparatory measures, mercury in conjunction with quinine was given, and in a very short time the system was fairly and comfortably affected, and the symptoms yielded rapidly without any injury to the constitution; but yet the rapid emaciation and diminished power which followed on the taking of mercury showed that, had not great care been taken, the remedy would have been as noxious as the disease; on the other hand, the cleaning of the tongue and the return of appetite, and loss of fever, told how surely and safely the combined remedies were doing their work.

There are many cases of secondary syphilitic affections which puzzle practitioners very much, and prove most tedious and refractory in their treatment. Mercury is given, the system is affected, the constitution gets disordered, but the disease yields not. Iodine is tried with some success at first, but the medicine loses its influence and the disease persists, or it vanishes and returns again. Many such cases turn out like this, whatever is done, and perhaps some accidental remedy completes the cure; but I believe much may be done by the careful and judicious use of mercury, combined with constitutional treatment by other remedies. Let us take, for instance, a case of iritis.

A wretched, gin-drinking costermonger gets an attack of iritis. He comes with his eye inflamed, the iris studded with nodules of lymph; his pulse is beating from 100 to 120, his tongue is furred, and he has no appetite. Mercury is given to him, and nothing else; his mouth becomes very sore, but his health gets more and more out of order; and, on looking at his eye, there is still the lymph on the iris, the great vascularity of the conjunctiva remains. The treatment is changed, but the mercury is not thrown aside, but it is given in small doses with quinine; the man is told to take some solid food and milk, and not to expose himself to variations of temperature. In a short time a change takes place, his health improves, and his eye begins to mend, and he gets cured without injury to his constitution.

Who has not seen rheumatic iritis again and again dissipated for a time by mercury, when given alone; and again and again recur, and not be entirely removed, until some other aid is given? Obstinate affections of the throat sometimes demand the assistance of the surgeon, and in these cases much discrimination is required to know at what period and in what manner to employ mercury. These generally appear in those who have been long labouring under venereal poison, and who are considerably injured in health. The iodide of potassium, which is found to be so invaluable a remedy in some cases of secondary syphilis, will be totally powerless in these instances; there is too much of the poison in the system to be exterminated by this drug alone. The surgeon may attempt to heal the ulceration by means of fumigations, but he will find this inadequate; after trying various measures for a time, recourse is had to mercury, which he was afraid to give at an earlier period; and this, in conjunction with tonic medicines and a nourishing regimen, brings about a cure.

There are certain affections which take place after an attack of syphilis in an unhealthy individual, the true nature of which the surgeon has great difficulty in detecting, and in finding out whether they depend upon the poison of syphilis or of mercury. I am speaking more particularly in reference to those cases where the patient has been long labouring under the disease, has either been taking large quantities of mercury at his own suggestion, or has fallen into the hands of some

●less practitioner or unmerciful quack; and consequently no accurate history can be learned. But, in many cases, sufficient can be learned to show that these symptoms are referrible to a copious and careless use of mercury; whilst, on the other hand, they may depend upon a too limited use of it. In the former cases we shall find the throat attacked, the cartilages of the nose diseased, and rapidly spreading ulcerations of the integument of the legs and chest; at the same time the general health is terribly shattered, and the whole system is prostrated by the action of a compound poison. In the latter cases the periosteum is attacked, especially that of the skull; and the skin is affected in the shape of papules or scaly spots; but the general health is not so much pulled down. The treatment in these cases should consist in giving mercury with iodide of potassium; but in the former, mercury must be studiously avoided, as it will only aggravate the existing evil; and we should have recourse to a general tonic and stimulating plan; the daily use of sulphur, tepid bathing, if the patient be not too weak.

There are many other points worthy of consideration connected with this interesting subject; but I shall now conclude, having strictly confined myself to that part which the heading of the paper indicates; and having endeavoured to show that in some forms of syphilis, extreme caution is necessary in the administration of mercury; that this remedy should be given in conjunction with general tonic medicines; and that its action will be rendered more safe and certain thereby; and, moreover, that a routine treatment will not do in syphilis, and that there is no disease which so much requires its treatment to be based upon scientific principles, and not upon a foolhardy empiricism.

July 3.

FOREIGN PRACTICE.

Reported for the MEDICAL TIMES by ALFRED MARK-WICK, Esq., Surgeon to the Western German Dispensary, and formerly Externe to the Venereal Hospital, Paris, &c.

A CASE OF VERTICAL (a) OR DE CHAMP DISLOCATION OF THE PATELLA, WITH OBSERVATIONS, BY M. PAYEN, M.D.

This species of displacement—which was first described by Moscati, illustrated by two cases by Monteggia, (b) called in question by Manne and Léviellé, considered impossible by Boyer, and which has been passed over in silence by Delpech, A. Cooper, Samuel Cooper, and Chelius—has been investigated by M. Malgaigne, in an excellent memoir, "Sur la Détermination des Diverses Espèces de Luxations de la Rotule." (c) Owing to its rarity, the recital of another case may be interesting:—

M. D., a strong robust man, about fifty years of age, was walking on the snow on the 15th of last December, when his right foot slipped backwards, thereby giving to the body a rapid rota-

(a) This designation, although commonly employed, is a very improper one. It is correct only where the patient is in the horizontal position—a situation in which he is never supposed to be placed in describing the anatomical or surgical regions of the body. [The latter term—*de champ*—signifies that the bone is resting on its edge. It has, as it were, undergone a species of *circumversion*, its external edge having become anterior and its articular surface turned outwards and slightly forwards.—TRANS.]

(b) This author states in his "Instituzioni Chirurgiche," on the authority of Manzotti, that a surgeon at Florence communicated a case of this kind to the Royal Academy of Surgery, who refused to believe it.

(c) *Gazette Médicale*, 1836. M. Malgaigne mentions only eleven cases of *de champ* luxation, and gives the details of eight. Since the publication of this essay, two other cases have been met with—one at New York, by Mr. Watson, and the other at Pittsburg, by M. Guzman.

tory movement in the same direction. Being on the point of falling, M. D. seized the railings that were within his reach, and thus immediately arrested, for the upper part of the body, the impulsion, which expended itself on the lower extremities. The violent torsion he thus experienced occasioned him very acute pain in the right knee.

It is quite certain that M. D. neither fell nor struck himself, as there was no mark upon the snow, and his clothes were not soiled. Persons came to his assistance and supported him, when he made a few steps to enter his house.

I was immediately sent for, and on my arrival found the leg slightly flexed upon the thigh, the knee extremely painful, and strangely deformed. The patella was placed edgewise in front of the condyles of the femur, so that its external border, from having become anterior, raised the skin; its cutaneous surface was directed inwards and rather backwards, and its articular surface outwards and rather forwards, while its internal edge rested firmly on the anterior part of the extremity of the femur, a little external to the middle line; the muscles of the thigh were powerfully contracted, the slightest movement was impossible, and every effort caused very great pain.

The patient having been placed in bed, with the limb resting on a mattress, I attempted to push the patella backwards by pressing the internal border from without inwards with my thumbs, whilst with the other fingers I brought the external border from within outwards, but without success. I then flexed the thigh upon the pelvis, the leg being extended, as recommended by Valentine, and again tried, but with no better result. I then had recourse to the very rational method deduced by M. Malgaigne from his researches, (a) and which M. Coze (b) had previously successfully employed in a case of *de champ* dislocation—viz., to forced flexion of the leg. But the first attempts occasioned such violent pain, and the contraction of the muscles of the thigh was so energetic, that I considered this mode as impracticable, and that I ought to abandon it.

Convinced, from the reasons given by M. Malgaigne, that the difficulty of reduction in this case was owing to the angle of the patella being wedged in what he calls the *subcondyloid space*, and being unable to dislodge it by flexing the limb, I imagined that I might arrive at the same result by the opposite proceeding, that is, by causing the patella to ascend. To effect this, the limb being extended on the bed, I ordered the patient to raise his leg as much as possible, my fingers being at the same time so placed as to cause the patella to turn over. The patient obeyed, and made a sudden and violent effort; the patella yielded and became somewhat raised, and then, with the combined assistance of my fingers, immediately reduced to its proper position. The knee immediately regained its shape, and was scarcely at all painful. The patient was ordered to keep in bed. During the first day the articulation was surrounded with compresses dipped in cold water. On the following day a swelling made its appearance on the inside of the knee, which gave the sensation of fluctuation. There was, however, no ecchymosis. On the seventh day the knee was restored to its ordinary size, and but little pain was felt on moving the patella from side to side. I surrounded the knee and the adjoining parts of the thigh and leg with a dextrined bandage, and the next day the patient was able to walk about on crutches.

On the twenty-sixth day I removed the bandage, and replaced it by a laced knee-cap. The patient was ordered to keep his room for a few days longer, and six weeks after the accident

(a) See his "Mémoire," p. 49, and his "Anatomie Chirurgicale," art. "Articulations du Genou."

(b) "Mém. de la Société Méd. d'Emulation," t. ix., p. 517, and the "Mémoire" already quoted, p. 68.

M. D. went out on foot with merely the aid of a stick. He is now quite recovered.

A few observations relative to this case may not be out of place.

1. At the time when M. Malgaigne published his essay, and from the facts which he had collected, we were justified in stating that the internal *de champ* luxations were more common than the external (5 to 3). The two new cases of MM. Watson and Guzman, however, restored the equilibrium. Now, the one above related places the majority on the other side, that is, in favour of the external dislocations (6 to 5).

2. Of the known cases of *de champ* luxation, those produced by mere muscular contraction are much the most rare, since only two of the ten cases I have just related—one external, and the other internal—are of this description. The one I have mentioned was external; and it seems rational to admit that the greatest number of dislocations of the patella, caused by muscular action alone, ought to take place in this direction, for it is to this side that the triceps tends to draw the bone, and we know that it is on this same side that what are called spontaneous luxations are always observed.

3. The above case fully confirms M. Malgaigne's ideas as to the cause of the difficulty of the reduction, and it is evident that the proceeding we adopted could succeed only by disengaging the angle of the patella from the subcondyloid space. As regards the mode of reduction, our case is very analogous to that of Monteggia (M. Malgaigne's sixteenth observation), in which the patella became spontaneously reduced during the efforts made by the patient in walking. In both cases the bone was dislodged from its wedged position by the same mechanism; we may, therefore, reasonably establish the precept, viz., to assist the reduction by making the patient stand up, or even by making him walk.

4. As regards the facility of the reduction, our case holds an intermediate position between the extreme cases; and we may mention that, of the eight recorded by M. Malgaigne, the difficulty was so great in four that, in one, division of the muscles and of the ligamentum patellæ was resorted to without success; in two others, the elevation was obliged to be employed; and that in a fourth the reduction was impossible. We may also add that in the case of M. Gagsan, the bone was not reduced till after the ligamentum patellæ had been divided, yet this division did not apparently facilitate the reduction.

5. It has been said that the greater or less facility in the reduction depends on the cause of the displacement, and that the luxations of the patella produced by muscular contraction are more easy to reduce than others. May not this depend on the action of the muscles alone not being, generally speaking, sufficient, unless there is some anatomical disposition to favour the displacement; and which, consequently, facilitates the inverse route which the bone has to pass through in order to become reduced? Still I may remark, that in one case where M. Cuynat was obliged to employ the elevator, the dislocation was occasioned by muscular contraction. However, notwithstanding that M. Malgaigne's opinion, as to the partial and spasmodic contractions of the triceps femoris being a cause of the luxation of the patella, is contested, (a) I, nevertheless, entirely coincide with it; indeed, it appears to me to be corroborated by the case we have related, for we cannot comprehend how there can be complete harmony of contraction in the inordinate and discordant movements above described. These isolated contractions of the muscular fibres appear to me incontestable; it is stated in all our treatises on anatomy, that when the arm is raised, the anterior portion of the deltoid contributes to carry it forwards, and the posterior portion backwards; the same, in fact, with numerous other muscles. We, therefore, see no difficulty in acknowledging the preponderating contraction of one portion of the triceps

(a) A. Berard "Dict. de Méd." in 30 vols., . xxvii., p. 646.

femoris, as a cause of certain dislocations of the patella; and M. Malgaigne has very truly affirmed that the simultaneous action of all the muscles of a joint tend to consolidate, and not to modify, its relations.

6. It has been stated that there may be some difficulty in ascertaining whether the *de champ* luxation is external or internal; in the above case, no doubt could possibly exist; and the patella, evidently placed outside the middle line, pointed out very clearly the direction of the displacement. I am not aware that it is the same in every case; still the examination of the surfaces of the patella ought to be an indication, as it proved to be in our patient.

7. As to the information said to be furnished by the extensor tendon and the ligamentum patellæ—the internal border of which, being more tense, indicating an internal luxation, and *vice versa*—we have endeavoured in vain to appreciate its value; the ligamentum patellæ, when forcibly stretched, did not present any distinct or appreciable border.

8. Lastly, in the details I have given, I have mentioned that the surfaces of the patella had become placed not merely laterally, but that the posterior was external, and at the same time rather anterior; and the anterior internal, and a little posterior. This disposition was sufficiently marked for me not to hesitate to admit the possibility of the *upside-down* luxation; and I am convinced that, if M. D. had fallen on the knee after the displacement of the patella, this dislocation, in a more or less complete form, would have been the result (a)—*L. Abille*.

I have lately met with a similar case in one of my colleagues, who has been under the care of Professor Blandin. In both, the accident was occasioned by a fall on the knee. Dr. P. can now walk without much difficulty.

Médecine.

19, Langham-place.

THE PHYSIOGNOMY OF DISEASES OR SEMELOTICS IN THEIR ASSIMILATIVE CHARACTERS.

By GEORGE CORRE (Author of "A Popular Treatise on the Kidney," &c.), of the Middlesex Hospital.
[Illustrated by Portraits of Cases.]

INTRODUCTION.

In the course of nearly sixteen years' residence in the Middlesex Hospital, where twelve or thirteen thousand patients are annually relieved, it has often struck me, amidst the vast number of cases of disease by which I am surrounded, that such stores of information as are therein presented to the eyes of students, ought not to be allowed, as it were, to run to waste; but that gleanings might be largely collected, in order that the general features of this mass of knowledge might be recorded in a somewhat profitable manner.

Amidst the continual change of patients whom I have to receive and ward, and the progress of whose diseases I have to notice in the course of my duties, in two, three, or more diurnal visits to the medical wards, it may be seen that very rare cases pass on, cured, or otherwise ending in death. Common cases occur with exceedingly curious symptoms superadded to the ordinary ones; all of general interest to the medical man. They are seen, and they vanish, to make way for another dense mass of objects, presenting more or less of curious feature to the observant eye; and thus the year rolls out and numbers its ten, twelve, or fourteen thousand in our institution, and like the shores of the ever-full ocean, the tide ebbs but to fill again.

I have been solicited by a valued friend to put

(a) I may take this opportunity of mentioning a very uncommon accident of the patella, viz., the rupture of its tendon. The patient was an aged female, and mother of one of my friends, who is the director of the hospitals. The tendon appeared to be torn from its attachment to the tibia, rather than ruptured in its centre. The knee became completely ankylosed.

some of these pictures on paper, in connection with my own ideas and remarks; and I feel inclined, if my life should be spared by Him who holds our breath in his Divine hand, according to His own declaration, so to do. And here I must observe, that though I love my profession, and will give place to no man in admiration of the splendid talent and skill which adorn this hospital, as well as many other metropolitan institutions of the same kind, or the distinguished names which shine in private practice, I, nevertheless, am bold to declare, that I consider God alone The One who kills and who makes alive. (a) Who wounds and who heals; and in these days of profanity on the one hand, and of hypocrisy on the other, I consider that a man should speak plainly, that the principles which sway him may at once be known; and herein God must be magnified, since, of ourselves, we should shrink from the expression of religious influence, unless the Lord bestowed His powerful grace accordingly.

Thus, my belief is, that the Lord Jehovah blesses the prescriptions, and advice, and experience of a talented physician, when such is His Almighty will; and that, on another occasion, with the same form of disease, the patient of the same sex and age, with symptoms closely similar; with the same care bestowed by the same accomplished physician—that, notwithstanding, the patient dies; because man has an appointed time for death, and go he must when it comes, whether suddenly, in the pride and vigour of his step, or slowly, by the attenuating disease. Thus, I desire to give the glory to God which is His due, in His designs, and in His workings in Nature, Providence, and grace; and I believe His government of every object, however minute, or however immense, to be as absolute as it is wise; and as good as it is perfect; and so will be found to be, at the winding up of all things in the great day.

(a) The Lord God, as a Sovereign, gives command. He wounds by instrumentality, and heals, in the tender mercies which are over all his works, at once, by his own word. "He sent his word and healed them" (Psalm cxlvii.) has a temporal as well as a spiritual meaning. It appears from scripture, that the enemy of man is empowered for the work of death and disease. The Lord gave leave, and "so went forth Satan from the presence of the Lord," commission in hand, to smite with sore diseases, but not to kill. (Job i. &c.) Also, the Prince of Life and Glory, the Lord Jesus Christ, as recorded by the Holy Ghost, said, "Ought not this woman, whom Satan hath bound" (with some sore affliction of body), "lo! these eighteen years, to be loosed from her infirmity," &c. The same enemy, through sin, has the power of death, when leave is given from Him "who holds the breath of man in his hand," thus, "him who has the power of death, that is, the devil" (Hebrews ii.) Satan had permission and command, first, to slay and to destroy what Job had, children, servants, cattle, &c. He was restrained from touching Job. Afterwards he was empowered to touch Job with disease, but to withhold the stroke from "his life." (Chaps. i. and ii.) In earthly matters, a master or governor does not himself destroy—he gives the order to the executioner; or he lets loose upon one animal another whose nature it is to wage war against the first. Thus the dog baits the bull, worries the fox and hare, and destroys the rat, &c., by command of him who is said to do it himself—as the mouse is let loose upon the cat by the owner's command or hand; they act but in agreement with their destructive natures. The Lord wounds by instrumentality: as in the pestilence, famine, or the sword, &c. &c., whether it be against a nation or an individual: thus, the King of Israel being offered one of these three, the pestilence was chosen, and it fell upon the nation, destroying 70,000 men. He heals by His own Almighty word: "He sent his word and healed them, and delivered them from their destructions." (Psalm cxvii.)

In the course of my experience I have often had occasion to remark one point especially, to which, indeed, my attention was early led by my valued and talented master, Dr. Latham, whilst he held the office of physician to St. Bartholomew's Hospital, where I was a student under his tuition; namely, the physiognomy of disease in its assimilative character; and since I have entered the Middlesex Hospital, I have had occasion to observe the fatal results which have taken place too often, from the medical man out of doors having mistaken one disease for another, and treated the patient accordingly; so that he has applied to us for advice when it was no use.

When, therefore, preparatory to the visits of the physicians, I have had to make mine, I have endeavoured to impress upon the minds of those pupils who were pleased to accompany me, the very great importance of the study of disease through the index of the countenance—the features of the face—the air, gait (if able to walk); the manner, cast, colour, turn, expression, silent or speaking language, implied or indicated by words or signs, so that almost on the first glance one might say, "hepatic," "cardiac," "renal," "uterine," "cerebral," &c. &c.

It is related of the celebrated physician Andral, so famed for decision upon physiognomical presentation, that the moment his penetrating eye surveys the features of a patient who has some hidden disease stealing on, he will immediately detect and declare it to those around him; but especially keen is the discrimination which he is able to make from the eye of a fever patient who has passed a tranquil and refreshing night, or a restless and disturbed one.

The medical student who carefully notices the cases in our London hospitals, and who is not altogether ignorant of country practice, may be struck with one thing: the fierce aspect of many diseases which, out of doors or in the provincial small towns and hamlets, bear generally a mild and tractable character.

The reasons I conceive to be mainly these:—First, that hospitals, and metropolitan ones especially, contain the working and lower classes of the people, who live in unwholesome kitchens, feed upon the most unhealthy articles of diet, and allow their bodies to be filthily dirty beyond conception, however smart and neat the outside appearance. (a) These persons are more than ever brought up with unbridled passions and tempers, in which they indulge in after life, carrying their whims, fancies, and leadings, into any and every extravagance, to the total neglect of all good advice from wise relatives or superiors. Secondly, that this class of persons are immoderately fond of all medicines or compounds, quack or otherwise. (b)

(a) A butler, some time since, who was in the habit of guining a livelihood by attending large dinner parties as a waiter, fell down in a fit, whilst so engaged at the table of one of our splendid mansions at the west-end of the town. On his admission here, his head was ordered to be shaved, when he was found to be literally overrun with pediculi and pruriginous eruptions.

A married sempstress was under the care of the physician, as an out-patient, with the most inveterate form of scabies and itch combined, whose employment was to attend daily in one of our largest hotels at the West-end, to keep in order the stock of linen; and this she did during the whole time she was under treatment, and prior to her attendance as a patient.

(b) There is hardly a servant in private families who can bear to throw away a few pills, or some untouched draughts, &c. A lady, whom I know, ordered her own maid to carry down some draughts in phials, to pour out the contents, and to put away the bottles. The cook, seeing her take the phials to the sink, declared it was shocking extravagance to throw away physic. "Do give me some of it," she said. She accordingly emptied four bottles into a basin, and drank off the whole quantity; then, shaking her head, she fetched a raw carrot from

Every neighbour has a remedy to recommend for every ache and pain, and the one person is no readier to recommend, than the other is to try the same. These persons physic themselves, too, with enormous doses of such things as salts, sulphur, calomel, and purgative pills, &c. &c.; and they often insist on being bled without any advice whatever; they go to the patent-medicine warehouses, and buy any nostrum whose title has struck them outside the window, or which some friend has suggested. A young woman was lately brought into our wards in a frightful state of pyralism, from only taking two powders, bought in such haphazard way at a patent-medicine warehouse near at hand. Thirdly, when these people are downright ill, and the disease is set up, in however severe a form, they still go on, utterly reckless, apparently, of life or health; and the friends, however ready with their tears for their sufferings, are just of the same stamp with themselves. They have been known to bring a heavy-crusted meat-pie in their arms, with a baby seated on the top of it, in order to feed a sister just merging from the most severe attack of gastro-enteritic fever. A man has brought a beefsteak pudding, in the crown of his hat, to his wife, ill with pneumonia; and the wife has brought her husband pork and greens in a teapot, and they have been detected eating them together, although the patient has not recovered from a dangerous attack of enteritis.

A porter is not always vigilant, nor is a nurse always faithful to her duty; it would be scarcely credited, if a long list of the contraband eatables, which are hebdomably seized in our public hall, was submitted to an intelligent mind. The cant phrases, "Poor thing, it will do him, or her good, if he or she can only get it down," has beguiled many; and even an apoplectic man has had some article of cookery surreptitiously brought in and stuffed down his throat by this ignorant, mock, and wicked pity. We have not only found out and detained every kind of improper food at the entrance of the hospital, but we have also detected the same in the hurried circulation, the oppressed breathing, the swollen epigastrium, and the hot skin, with returning delirium, in the patient. And, if such be the case where so much pains are taken to compel a proper regimen, what must there be of reckless cramming of the stomach where such restrictions exist not, as in the little private home! Thus, without restraint on the passions, unbridled tempers, full indulgence of appetite in any eatable or ardent spirit that is within the means to obtain, disregard of the best medical advice and orders, wicked folly of friends and their example, and a readiness to swallow any nostrum recommended by the ignorant, we may form some notion why diseases are seen to assume the appearance they do in our institutions; joined to these, also, may be added constitutions unstrung by the free use of tea and ardent spirits, general irregularities, with poverty, and anxiety, and care.

On the other hand, the general practitioner expects, and for the most part obtains, in private practice the most implicit obedience to his rules and orders. He also, with the physician, has another advantage, that in the ushering in of a

the pantry and ate that, to take away the nausea!

The more medicine our patients have, the better pleased they are. It is most amusing to see the scribe of the ward, with spectacles on his nose, poring over the medicine tray, with the crowd around him, while he eagerly looks over the bottles, remarking, "There is some nice red medicine for you, Mr. —;" "that is strong stuff for you, Mr. —;" and "here's your new medicine, Mr. —," &c. &c.; and sometimes our physicians order a dose immediately, for an out-patient, and it is laughable to see the satisfaction with which an Irishman, especially, swallows down the draught, and drains the glass to the very last drop; saying on one occasion, "Thank ye, your honour; that's the first bit of victuals I've had these two days."

disease he is applied to; and, although the perfectly-developed features of a serious disorder may not be as yet so portrayed as to enable his mind to catch the real character of the approaching disease, yet experience and a quick eye master even this difficulty in time; and the sickening stage has also its small index, however minute the points of the dial, and however illegible the characters. The practitioner has an opportunity of witnessing the early stage of every disease, whilst these accessions are rarely met with in an hospital. Here we see disease at its height running down to death, or disease at its height running up to convalescence; but disease at its height traced up to the spring-head of its onset we rarely have a full opportunity of viewing. It seems, therefore, probable that the main reason why the private practitioner may be often misled in the formation of a correct diagnosis of an approaching malady is, that he is perplexed by the presence of so many minor symptoms and feeble outlines of the disease; whilst the hospital practitioner has the privilege of viewing the broad features of the enemy, and is, therefore, not led astray by the contradictory statements and feelings of the patient. In short, I think it may be said that the diagnosis of diseases in hospital practice is less perplexing to the private practitioner than is the detection of the trifling *malaise* in private practice by the hospital practitioner.

The advantages of both experiences combined must be very great. The hospital physician and house-surgeon alone enjoy them. It is true that the perpetual pupil engaged for years in private practice has free access to the wards of his pupilage; but with him time cannot be spared for these visits. Neither is his duty involved in regular attendance, as is the case with the hospital physician and surgeon.

The fastidiousness and folly of the rich and noble classes of society, and their terror of death, which the poor so often look upon with recklessness or a stupid indifference, induce them to send so frequently for the physician, when scarcely any bodily complaint exists. A friend of mine was requested to send an eminent physician to a young lady making very great complaints of indisposition; the noble-minded man cast his eye on the lady, asked a few questions, and then turned away, to the astonishment of my friend, who, on taking him aside, heard him declare there was nothing whatever the matter with the supposed patient. It was entirely put on; and very angry was she, when informed that the physician, who knew her better than my friend, said he should call no more. Now, the fond mother of that young girl would most willingly have paid ten or twenty guineas in fees, for her darling and only daughter; but Dr. — was too noble to pander to the folly and vices of persons in high or low life. Indeed, nothing makes those of all classes more enraged than to tell them they are very well, when they positively declare, and insist upon it, that they are very ill. Notwithstanding which, the truth is The Truth; and that lip which flinches least from declaring it will, in the long run, obtain most of honour, confidence, esteem, and respect, from every liberal-minded employer.

It has been remarked that diseases are, for the most part, somewhat advanced when patients are admitted into the hospital; some of them have been sadly neglected, or mistaken by a general practitioner, who having, unhappily, set out in life by mistaking mere fancy for fact, or bent of genius, has fixed on the profession of medicine; in which hard study, consequent rich harvest of knowledge, with clinical experience in all the wards of an hospital, have been held as disagreeable works of supererogation. (a)

(a) We have repeatedly admitted the lowest form of typhus, amongst the ill-fed Irish, from the wretched haunts of St. Giles's, who have been seen by some such awkward practitioner in the first stages of the fever, and have been largely bled—once, twice, or even oftener; whilst others, who have laboured under acute pneumonia, have

MIDWIFERY. — SHORT UMBILICAL CORD, WITH RUPTURE ON DELIVERY.

By J. W. REED MACKIE, Esq., Cupar, Fife.

Mrs. H. was seized with labour pains on the evening of June 20. They gradually increased in severity till the morning of the 21st. About ten a.m. I was sent for, and on my arrival, about eleven a.m., I found her in bed, pulse natural, pains recurring regularly, &c. &c. On making a vaginal examination, I found a large primary syphilitic ulcer on the right labium, the vagina well lubricated, os uteri nearly dilated, membranes not ruptured, and the head presenting in the first position. I may state, the head was well descended in the cavity of the pelvis, and that the bowels and urinary bladder had been frequently evacuated. Her former delivery was natural, but tardy.

The pains continued to increase in severity, the head during each was pushed upon the perineum, and as the pain subsided it (head) gradually receded high in the pelvis. This state continued for about three hours, when the membranes burst, and the head was pushed partly through the outlet; a very strong pain succeeded and drove the head powerfully through the vulva; the body immediately followed; a tremendous gush of blood at this moment took place. On examining the child, I found the umbilical cord to have been torn about one inch from the abdomen; I tied this. The child was quite blue and livid, and covered, especially on the head and chest, with the copper-coloured eruption. Finding the hemorrhage from the mother still continuing, I introduced my fingers into the vagina to get the cord tied; the cord I could not feel, but had recourse to cold applications, which, to a small extent, proved hemostatic. Ringing in the ears, headache, and great sickness now came on. She had a little wine, the abdomen rubbed and a bandage applied, and 3 jss. of the liquor secale cornuti of Batley (the best and most certain preparation of the secale I have yet seen—indeed, I think superior to ergotine itself).

In about five minutes, contractions of the uterus now occurred, and on examining again I found the torn cord hanging through the os uteri. The placenta shortly followed, by a little manipulation. The hemorrhage ceased. On examining the placenta it was in some parts quite hard, indeed ossified (a state which exists more frequently than what many medical men will credit); in others quite soft, like jelly. I measured the cord, and found it to be only four inches and a quarter in length. The child died next day. The mother did well, and is now following her usual avocations, although under treatment for syphilis; I may state, the father is also under treatment for "secondary symptoms."

In this case I am inclined to believe that the cause of rupture of the cord proceeded partly from the syphilitic taint, and partly from its extreme shortness.

PRACTICAL OBSERVATIONS RELATIVE TO THE MANAGEMENT OF THE INSANE, AND THE MODE OF GOVERNMENT PURSUED IN OUR PUBLIC HOSPITALS FOR LUNATICS.

By WILLIAM SMITH, M.B.C.S.E.,
Formerly House-Surgeon to the Lincoln Lunatic Asylum,
Member of the Association of Medical Officers of Hospitals for the Insane.

(Continued from page 274.)

I have in a former paper expressed an opinion that the commissioners in lunacy have exercised a sound discretion in recommending to the Lord Chancellor "That in any county asylum or hospital hereafter to be erected, into which

been allowed to run on from hour to hour, and day to day, with some opening pills and a dose or two of salts! Such gentlemen frequently send their diagnosis with the patient, and, on hearing the real disease declared, are not satisfied with our treatment or our report of the case.

curable lunatics (either alone, or together with incurable patients) shall be received, the number of patients shall not exceed 250 in the whole." I will now endeavour to adduce such arguments as may prove the necessity of not exceeding that number.

Every one, I think, conversant with the past history of legislation in our large public asylums (more particularly those of Hanwell and Lincoln) will admit the necessity of an entire unanimity of feeling amongst the medical officers of an hospital for the insane; without any desire of making unpleasant personal attacks upon the management of any particular establishment, I consider that the subject which I have taken up perfectly justifies me in mentioning any asylum which may strengthen the arguments I am attempting to prove; my object is to benefit the insane and make public any improvements in practice. If it be admitted, then, that unanimity of feeling amongst the officers of an hospital or asylum is absolutely necessary to the carrying out of any system of management (be it non-restraint or any other), what, let me ask, can be more effectual than placing the executive administration in as few hands as possible? At Lincoln, where there is an honorary and unpaid medical staff of three physicians and three surgeons, in addition to a salaried house-surgeon or director, things have worked very badly, and frequent changes of the chief executive officer have taken place, which undoubtedly has had a prejudicial influence over the welfare of the patients. At Hanwell, with a vast assemblage of 1000 patients, and a consequent amount of attendants (or, to use the elegant phraseology of the commissioners, keepers and nurses), two resident medical officers were found inadequate, and what took place is recorded in the following words by the commissioners in lunacy:—"In the case of the Asylum at Hanwell, the visiting justices have lately appointed a gentleman (formerly an officer in the army), who has had no previous experience in the management of the insane, as the governor. The appointment appears to have become necessary in order to preserve good order in this large establishment; and, for that purpose, the governor has the power of suspending, not only the servants, but even the medical officers and matron of the asylum. He has also the entire control over the classification, employment, amusements, instruction, and general management of the patients, both male and female, subject only to the general control of the visiting justices." This singular arrangement of course could not continue long, and was speedily abandoned as impracticable. Now, in correcting abuses, I am an advocate for applying remedies at the fountain-head; in plain truth (as I have before asserted) the Hanwell establishment is much too cumbrous to work well under any system of management whatever; and this unpalatable truth will, some day or other, be exhibited in such a light as to force conviction even upon the minds of the Middlesex justices. If an establishment (my remarks will apply equally to hospitals for the sick) do not contain more than 250 patients, one resident surgeon is amply sufficient, and in this individual should be vested the absolute control of the attendants and household. It is a curious circumstance, and somewhat remarkable, that the medical officers and attendants in those asylums advocating moderate restraint should retain their appointments much longer than those where non-restraint has been exclusively adopted. I do not profess to give any explanation, but such undoubtedly is the fact. Where any difference of opinion is known to exist amongst the managing committee or medical staff of any lunatic hospital or other medical charity, the task of regulating the attendants and household will be proportionably increased. I state this as the result of personal experience. On being elected house-surgeon to the Lincoln Asylum, in April, 1840, I found that establishment in a state of chaos and confusion. The medical officers were at issue on the important subject of mechanical restraint, and, as a natural consequence, the lay governors were divided in opi-

nion ("for who shall decide when doctors disagree?"). Not having had any practical acquaintance with insanity, I had everything to learn, and much to combat with (for to the uninitiated the discipline and regulation of the attendants is the greatest labour). These unfortunate divisions continued for two years, when, having made myself thoroughly acquainted with the practical working of the house, and trained upon an entire fresh set of attendants, I declared myself in favour of the system of non-restraint, from a conviction of its entire practicability and humane tendency. From this period our difficulties gradually disappeared, and I had further the satisfaction of discovering that, from observation of the working of the asylum whilst under my superintendence, Dr. W. D. Cookson, one of the physicians, became a convert to the system of non-restraint. These circumstances are brought forward now, not from a desire of ripping up old grievances, but to demonstrate the imperative necessity of one animus prevailing throughout the staff of any hospital for the insane. Had there been no intestine discord at Hanwell, it is extremely probable that the valuable lectures of Dr. Conolly might not have been so clear and instructive. Much still remains to be done with reference to the attendants in all establishments for the insane: we want persons of superior education and good moral character, in place of a race of giants and amazons. One might almost imagine, on visiting some institutions, that the Empress Catherine of Russia had been consulted in the selection of "these nervous six-foot fellows."

Mr. Hill, my predecessor at Lincoln, has put forth a dogma on this subject to which I can by no means subscribe, and possibly my practical experience and powers of observation are not inferior to his own. I look upon the attendants of an asylum as instruments for great good to the patients, or the reverse: if they are well-informed, humane, and enthusiastic in the performance of their duties, they are very powerful instruments for good in the hands of the medical superintendent; to encourage this spirit, they should receive liberal wages, be comfortably treated in every respect, and have frequent leave of absence (within proper restrictions) since contact, during any lengthened period, with the insane has a depressing, though, at the same time, irritating effect upon the mind of some persons. Every inducement should be given to retain officers and attendants in an hospital for the insane. If officers and attendants are continually going and coming, the evils will affect the patients more or less. In establishments where such changes are unusually frequent, there is a defect somewhere. "Something is rotten in the state of Denmark."

I have spent considerable time and some money in inspecting many of our largest and best-regulated hospitals for the insane, and, not being officially connected with any establishment now, I feel myself perfectly free to express my sentiments without any reservation whatever.

With reference to officers and attendants being married or single, I consider it very desirable that the resident surgeon should be a married man, and that his wife should discharge the duties of matron; a neglect of this arrangement has been one cause of the frequent changes at Lincoln:—this circumstance, together with the unwarrantable interference of certain individuals with the executive government of the institution (in the intervals of the weekly boards), induced me to throw up my appointment at Lincoln: a step which I have ever since deeply regretted, as the treatment of insanity has now been for more than seven years my favourite study.

To prove that my views on the point I forenamed are in accordance with the result of experience, I would direct attention to the asylums of Northampton, Glasgow, Wakefield, Gloucester, and Nottingham; in these establishments, which in point of excellent management are first and foremost, the medical superintendents are married men; some of them of long

standing, and, what is still better, they possess the entire confidence and esteem of their respective governing bodies. They have grown grey in the service—a circumstance alike honourable to themselves and creditable to the establishments over which they preside; but if we turn to some other asylums, with whose management I am thoroughly conversant, we shall find a different state of things: the public benefit is sacrificed at the altar of personal ambition; individuals who have yet to learn the difficult task of governing their own tempers and passions arrogate to themselves the right of controlling the actions of a public officer; if he have the independence to resist, disagreeable regulations are imposed, and his comforts, and authority over the establishment, are curtailed as much as possible (and here let me observe, the rules and regulations of certain establishments have been constructed with a lawyer-like craft and subtlety known only to the tortuous mind of an Old Bailey practitioner); if, on the contrary, he submit (the rubicon once passed), one act of tyranny follows another, until, instead of being the executive head of the establishment, the quondam director sinks into the abject tool, the mere puppet of a restless, unprincipled agitator. Dr. Conolly, in his usual masterly manner, has vividly portrayed the evils resulting from the control over the attendants being placed in other hands than that of the resident medical officer. Even the rules of the Lincoln Asylum (inconsistent as they are on some points) declare that "the attendants and servants shall obey the orders of the house-surgeon and matron, as the master and mistress of the house;" but where the surgeon and matron are not man and wife, there is a great chance of differences arising between them, in which case each officer will have his or her partisans—a state of things wholly subversive of sound discipline.

Where the responsibility rests, there should be the power. If the visiting physician and resident surgeon pull well together, the institution will prosper; but if (as obtains at Lincoln), there be more than one physician, and these unfortunately differ on important points of treatment, how is the resident surgeon to act? "We cannot serve God and mammon." Facts are always preferable to mere assertions. Now, what has latterly occurred

at Lincoln? Why, the physicians are directly at issue, not on trivial points, mark you, but on subjects of vital interest to the insane: one month the patients are regaled with porter and wine, sedatives are prescribed, and exclusive classification is adopted; the next month, before the physician can have time to witness the effects (unless we are to suppose that the physicians see each other's patients on the sly), their allowance is knocked off and the opiates are discontinued; now, are we to presume that both doctors are right, or both wrong? Verily, it would puzzle Hudibras to solve this problem! Allow me to solve it in a different manner. Pack off two of the physicians (they might toss up, heads or tails), and place more authority in the hands of the house-surgeon—he is never little better than a cipher; and as to the "Book of Regulations," verily, my head aches now at the very recollection of that "chaos of impossibilities."

In favour of small asylums, I might mention the district asylums of Ireland, which, I understand, do not accommodate more than 200 patients. The hospitals in France have not answered so well as ours in consequence of their extreme magnitude.

In the Seventeenth Report of the Lincoln Asylum, page 29, there is the following foot note:—"We hope the time is near when the conviction will be more strongly felt than it has hitherto been, that the ultimate success of an institution in which human beings are assembled together, whether for instruction, support, correction, or physical cure, must depend almost, if not entirely, on the strength of character and moral fitness for the situation of the individual who is placed at its head. Whether it be a school, a workhouse, an asylum, or a prison, no committee of managers, or set of visitors, can ever hope to be able to bring it into a thoroughly prosperous state,

unless their intentions are seconded and carried into execution by the individual who is in reality the executive head of the whole."

With the sentiments herein expressed I fully concur, and I have had ample opportunities of judging in such matters whilst acting as house-surgeon to the Lincoln Asylum and County Hospital at Lincoln, and subsequently as medical officer to an extensive poor-law district and work-house in Hertfordshire.

I am further of opinion that our public medical charities might be rendered much more effective to the sick poor if, in place of the present mischievous system of having a numerous unpaid medical staff and an inexperienced salaried medical officer, the resident surgeon were an experienced man, and authorized by the rules to act in the generality of cases. All the medical officers of a public charity should be salaried officers, and elected by concourse. The reports of our public hospitals might, in proper hands, be really valuable documents. The physicians and surgeons, according to the present system, are not paid, therefore, they will not be at any trouble, and the task usually devolves upon the house-surgeon, who is for the most part a raw hand, fresh from his alma mater!

In "The Provincial Medical Directory" for 1847 (pp. 337, 338) are the following observations:—"The hospitals in Germany are always supported by the town or government; the mere administration is not carried on by a lay committee, but it is entirely intrusted to the medical staff. The head physician, or head surgeon, is appointed director, and generally resides in an adjoining building, or near the hospital, and is held responsible for the proper administration of its medical and general affairs. All medical officers, from the director to the house-surgeon, are paid for their services, in such sums as would enable them to maintain their respective stations without any private emoluments. For although the present career of the former, and the future career of the latter, are greatly benefited by their appointments, still this would never be deemed a sound reason why the time and the services they give up to the state should remain unrewarded. If, however, German practitioners would consent to fill these situations gratuitously, that is to say, to buy these situations for such annual sums as are equivalent to their services, the offers would not be accepted, for the authorities would fear lest the unpaid should be considered secondary to the remunerated occupations, or lest the situation, so ardently desired while in prospect, might be considered irksome when obtained, and lest the institutions should lose the right of claiming the utmost exertions from those who devote their skill as charity." Are not these arrangements infinitely preferable to our own? No sooner do our house-surgeons become thoroughly conversant with their duties, and therefore of real value to our sick poor (the parties for whose benefit these noble charities were ostensibly endowed and supported), when hey presto, they fly off into private practice, or elsewhere, and are succeeded by other novices. Until late years (the change has been obtained by the comments of an independent medical press) it was not deemed necessary to have a qualified resident surgeon at Guy's Hospital, containing 600 beds; patients were bled by dressers (*pueri indocti*), and the brachial artery might perchance be punctured; and if that learned Dogberry, the steward, willed it so, no inquest was deemed necessary, it was, perhaps, considered "*justifiable homicide*;" our youthful disciples of *Esculapius* must have subjects to exercise their skill upon, and why should not the poor and destitute furnish the materials?

It is truly lamentable to observe in this enlightened age and country the apathetic indifference to human life exhibited by our legislative bodies and the public generally. In any matters bearing upon pounds, shillings, and pence, what lynx-eyed vigilance is displayed in investigating even the most trivial minutiae! *exempli gratia*: observe the critical acumen displayed by assurance companies; but let a man's life be at stake, or his health seriously impaired, the first designing

vagabond, or illiterate pretender to medical science, is at once installed master of the ceremonies, especially amongst our aristocrats, hinc omne genus, mesmerizers, homoeopaths, &c. &c.

But to return to the insane. Many persons (amongst whom I will enumerate the learned commissioners in lunacy) are impressed with the belief that a quantity of physis is requisite for the cure of insanity. This I consider to be a mental delusion; it may possibly savour of presumption in me to call in question the opinion of such learned Thebans; unfortunately for their theory, however, my sentiments on this point are in unison with those of gentlemen who have spent the best part of their lives in "ministering to the mind diseased." I do, therefore, assert that very many cases of insanity are cured without a single particle of physis. The principal indication, then, in a case of insanity is a speedy removal from home, for, as it is natural to suppose, the maniac submits with a very poor grace to any control exercised by his friends, or deputed to servants. Then, again, until the publication of Dr. Conolly's practical lectures the majority of medical practitioners were wholly ignorant of the treatment of insanity; or, still worse, their ideas were based on false premises; insanity was viewed by them as an inflammatory affection of the brain; and bleeding, blisters, setons, tartar emetic, and low diet, with other antiphlogistic remedies, were vigorously enforced by these zealous but misguided individuals. In our public hospitals for the insane a very contrary practice is adopted, and I have always found it attended with the happiest results.

King-street, Belper, June 1.

(To be continued.)

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of July 12; M. BRONGNIART in the Chair.

CONGENITAL OPACITY OF THE CORNEA. By Dr. TAVIGNOT.—On June 15 a child, aged ten months, was presented to Dr. Tavignot. The eyes were in the following condition:—"The eyeballs were of a natural size, their form being, however, more regularly spherical than usual, and both being agitated by that sort of lateral movement called nystagmus. In all its extent, with the exception of a transparent zone one line in breadth at its circumference, the left cornea was completely opaque; on the right side the opacity was limited to the very centre of the membrane, one-third of which only was impervious to light. No traces of morbid vascularity could be detected, the lids being natural, and showing no marks whatever of previous ophthalmia. The iris, in each eye, had almost completely disappeared, being reduced to a small greyish line, in contact with the ciliary ligament. The pupil appeared to be perfectly insensible to the influence of light; vision existed on both sides, but too strong a light caused photophobia, and produced sneezing. The infant was born in this condition, and had never since birth suffered from ophthalmia. Examining the case in an etiological point of view, Dr. Tavignot remarked in his communication that the alterations might be referred to one of two causes, viz., either to an arrest of development of the eye, in consequence of which the cornea preserved in a permanent manner the temporary opacity existing provisionally during the first months of intra-uterine life; or to inflammations attacking the cornea during gestation. Dr. Tavignot was inclined to attribute to the latter cause the condition of the eyes in the present case.

DESTRUCTION OF CALCULOUS CONCRETIONS WITHIN THE BLADDER. —M. Phillips forwarded on this subject a paper, in which he recommends the association of galvanic power with chemical solvents, for the purpose of destroying the cohesion of calculi. The fluids which M.

Phillips adopts are either acid or alkaline, in the first case consisting in 100 grammes of water acidulated with one gramme of sulphuric acid; in the second, constituted by 0.50 centigrammes (10 grains) of potash in 200 grammes (73) of water. The instrument, resembling in its form M. Heurteloup's percussor, contains a sound adapted for receiving a double stream of fluid, and the wires to be placed in communication with the poles of a galvanic battery.

ACADEMY OF MEDICINE.

Meeting of July 13; M. BROIN in the Chair.

THE BITTER TASTE REMOVED FROM EPSOM SALTS.—M. Soubeyran communicated, on the part of Mr. Combe, a paper, in which is mentioned a new method calculated to deprive sulphate of magnesia of its bitterness. Ten centigrammes (two grains) of tannin, added to the quantity of water necessary for the dissolution of one ounce of sulphate of magnesia, accomplish this purpose. In order to destroy the pungent taste of the tannin, it is only necessary to boil the solution with a small quantity of ground and burned coffee. The result is a pleasant mixture, the purgative effects of which are certain (a).

SCURVY AND TYPHOID FEVER.

M. Scoulteten, a military surgeon, related to the meeting the details of an epidemic of scurvy, which attacked the garrison of the town of Givet during the month of May. The 42nd Regiment of Foot, and the 2nd Cuirassiers, were both affected, though in a very unequal manner; two cases only having been observed in the cavalry regiment. All forms of petechiæ and ecchymosis were observed, from the smallest specks to the broadest hemorrhagic patches; febrile excitement was present only in the worst cases. A severe epidemic of typhoid fever had preceded the manifestation of scurvy in the garrison, and was referrible to the same causes—viz., bad ventilation and insufficient food. The patients were removed to a fort placed in more favourable hygienic circumstances, where they speedily recovered.

M. Rochoux remarked that scorbutus was evidently the result of the respiration of vitiated air—a fact proved by the total disappearance of the disorder from the cities of Paris and Strasbourg, since their sanitary improvements. But typhoid fever still existed in both places, and to a great extent; consequently, he would be inclined to adopt a different opinion from M. Scoulteten, and to say that the two disorders recognised different causes.

M. Moreau asked M. Scoulteten to explain a passage of his communication, in which he stated that the diseases were produced by insufficient food. Was it possible that the victuals distributed to the soldiers were so scanty as to produce these fatal results?

M. Scoulteten, in consequence of his official position, declined giving any explanations on this point. As to M. Rochoux's argument, M. Scoulteten would not deny that a vitiated atmosphere had a great deal to do with the production of scurvy; but the modification in the nature of the food had also considerable importance. Thus, in the penitentiaries, epidemic scurvy broke out when meat ceased to be given to the convicts, and was arrested only when animal diet was again allowed them. Besides, M. Scoulteten did not maintain that the causes of scurvy and typhoid fever were absolutely identical; but he contended that they were analogous, from the resemblance of their causes. Might not, also, an analogy of nature be fairly concluded to exist? The men were not crowded in the sleeping-rooms, and the cavalry soldiers

(a) Is it desirable to remove bitterness from Epsom salts? To this question we would be inclined to answer in the negative, as we have, in common with most practitioners, hitherto considered the bitter taste of the salts as a favourable circumstance, in consequence of which sulphate of magnesia may be classed with "tonic purgatives."—D. M.C.

mixed with the infantry, and were better fed; hence, perhaps, the great difference observed in the intensity of the disease in the two corps. With regard to the similarity of nature of scorbutus and typhoid fever, M. Scoulteten reminded the academy that, seventeen or eighteen years ago, he had laid before the society the intestines of animals in whom, by a peculiar diet, he had produced typhoid fever and ulceration of Peyer's glands; if, therefore, this disease could be produced at will, its causes must be known. If, in some cases, they escaped detection, it was because they were not sufficiently sought after.

Professor Bouillaud could see no analogy whatever between scurvy and typhoid fever; he had observed upwards of seven hundred cases of the latter disease, and not a single one of the former, yet, if they were produced by the same causes, this could hardly occur; besides, typhoid fever was by many deemed to be contagious, and no one fancied scurvy to be so; fever was present in typhus, and absent in scorbutus; in a word, the two diseases presented neither resemblance nor even analogy.

TUBERCULIZATION OF THE BRONCHIAL GLANDS, AND PATHOLOGY OF DROPSIES.—Such was the title of a paper read at the close of the meeting by M. Marchal (de Calvi). The presence of tubercles in the bronchial glands had hitherto been considered as a phenomenon special to infancy; M. Marchal related two cases in which the disease was observed in the adult, and in both death had been the result of compression of the air-tubes. In these two cases death was sudden, and could not be explained by insufficient oxidation of the blood. In the first case œdema of the superior parts of the body and ascites were observed, and M. Marchal took this opportunity to make some remarks on the general pathology of dropsy. In this particular instance the infiltration was referable to compression of the veins.

Meeting adjourned at a quarter past five P.M.

QUININE.—Dr. Landerer states that a nurse, having taken a large dose of sulphate of quinine, her suckling obstinately refused to take the breast. Chemical analysis demonstrated in the milk the presence of a notable quantity of quinine. The same author asserts that he detected the presence of the same substance in the dropical secretions of one patient, and in the tears of another, who was using sulphate of quinine in frictions. The rapidity with which the salt of quinine is now absorbed is now a well-demonstrated fact. We recollect a case of intermittent fever, which we published in the *Gazette des Hôpitaux* of July 12, 1841, in which this astonishing rapidity was exemplified and demonstrated in the most remarkable manner. On the first day of the treatment, ten minutes after the exhibition of 3j. of sulphate of quinine, four ounces of urine were removed from the bladder. M. Bouchardat, the learned chemist of the Hôtel Dieu, examined this fluid, and found that it contained half a grain of the medicine. With regard, however, to the absorption of the salt through the skin without the assistance of previous removal of the epidermis, the researches of M. Martin Solon and of M. B. have constantly yielded to those observers negative results. M. Landerer's assertion, therefore, is of great interest, but, in our opinion, requires further confirmation.

RAPID VESICATION WITH AMMONIA.—It is often requisite to obtain, in a very short space of time, a denuded surface, and in such cases ammonia is very generally resorted to; but it often fails in producing the desired effect on account of the rapidity of its evaporation. Professor Trouseau recommends the following simple plan:—Imbibe a piece of cloth of the size of the required blister, in ammonia; apply it to the surface, and cover it with a piece of coin of corresponding size, and within a few minutes the blister

meeting of the Institute, M. Nat. Guillot read a paper "On the various Proportions of Fatty Matter contained in the Lungs." They are more considerable before than after birth, and seem to diminish as the activity with which the respiratory functions are accomplished increases. At the period of parturition, before the lungs of the infant have breathed, they contain 10, 12, 15, or 18 per cent. of fatty matter; but when air has been admitted, the proportion of this matter in the diseased lung is no more than six per cent. In phthisis and pneumonia, when a portion of the respiratory organs becomes impervious to air, it becomes infiltrated with fat, and may contain as much as 30, 40, or even 50 per cent. of that matter. Section of the pneumo-gastric nerves and asphyxia have also appeared to M. Guillot to produce the same result.

CURE OF ANEURISM BY GALVANO-PUNCTURE.

CASE.—M. P. R., of the city of Plaisance, aged forty-one, of a strong constitution, was in the habit of playing with iron balls, which he threw up into the air and received on his extended arm. The consequence of this practice was a phlegmonous inflammation of the right forearm, and after the resolution of the phlogosis, a tumour of the size of a large walnut at the bend of the elbow. M. Restelli was called upon to attend the patient on September 27, and that physician detected in the swelling, pulsations isochronous with those of the arteries. Pressure above the tumour caused it to diminish, and, on the contrary, increased its size and the violence of its pulsations when exercised below. On examination with the stethoscope, a distinct *bruit de souffle* was heard at each arterial beat. An aneurism was therefore diagnosed, and M. Restelli determined to treat it by galvano-puncture. On the 28th of September, one element of the Bunsen pile was prepared, and two needles were introduced into the tumour. During twenty minutes a non-interrupted electrical current was passed through the aneurism, in which pulsation immediately ceased to be perceptible: its size gradually diminished, and on the 5th of November the patient was cured. Two very small eschars formed around the punctures made by the needles, and were healed one week after the operation.

M. Restelli recommends the use of a galvanic pile, composed of small but numerous discs, in order to diminish the development of heat, and at the same time to increase the coagulating power of the electrical fluid. The doctor also insists upon placing the needles in a direction contrary to that of the stream of blood to be arrested.

THE SUCCESSORS OF M. PARISSET.

The situation of "Secrétaire Perpétuel" of the Academy of Medicine is vacant by the death of M. Pariset: it is not only a most honourable post, it is also one to which a yearly salary of 6000 francs is attached. The following gentlemen are candidates for the office; it may not be uninteresting to our readers to become acquainted with the titles they bring forward in support of their claim:—

M. Bourdon, a physiologist, known by a paper on "Vomiting," and by two treatises of medical and compared physiology; also by a small volume on the German Spas.

M. Bousquet, more distinguished by the situations he occupies than by his scientific titles, is secretary of the council of the academy, and the author of a short paper on vaccine and on the cowpox, discovered at Passy in 1837.

M. Dubois (d'Amiens), the late annual secretary of the academy, has written an excellent treatise on general pathology, and a philosophical history of hypochondriasis and hysteria, and some other works of minor importance.

M. Mélier, the present secretary of the academy, has written very little; however, his memoir on diseases of the uterus, and his report on the sanitary conditions of the manufacturers of tobacco in France, have attracted much attention.

M. Réveillé-Parise, the feuilletonist of the "Gazette Médicale," a correct and not inelegant

writer, is the author of two volumes of physiology, of a treatise on the "Hygiene of the Eyes," and the editor of the "Letters of Guy-Patin."

M. Roche, one of the most ancient and ardent pupils of Broussais, has presided at the academy during the year 1846, and furnished to the medical dictionaries a large number of much-esteemed articles.

M. Rayer-Collard, professor of hygiene at the School of Medicine, the grandson of the celebrated political character of the same name. M. R. Collard is unfortunately afflicted with a disease of the spinal chord, which has, within two years, almost deprived him of the use of his lower extremities. This circumstance will, very possibly, plead in his favour. All would be happy to see his election produce upon him the same effects which history informs us were brought on in the case of Sixtus V., by his preference to the papal see, although that miraculous recovery can hardly be expected to occur a second time.

D. M'CARTHY, D.M.P.

Development of Bone in the Falx in a Case of alleged Homicide.—A man, a weaver by trade, was, in a scuffle, thrown against a pile of straw, and while down was pressed upon by another man. During this time he was unable to speak, and on getting up he declared himself very ill, and made frequent attempts at vomiting. During the next day there was occasional sickness, and in the afternoon he was unable to answer when spoken to. Within twenty-four hours after the violence done him he expired, having been comatose for some hours before. At the post-mortem examination, by Dr. Selkirk, of Carlisle, there were no marks of violence discovered externally; the lungs were gorged with blood, giving out freely, when cut, a frothy sanguineous fluid. There were some crude tubercles in the upper part of the right lung, and the trachea, from the mouth to the bifurcation, was filled with a frothy sanguineous serosity. The brain was congested, otherwise healthy. Beneath the dura mater there was an extravasation of blood on the surface of both hemispheres: that on the right amounting to an ounce; that on the left more diffused, and somewhat smaller in quantity. Between the hemispheres there were found three pieces of bone, two being small, the third about half an inch. The heart was empty.

Malignant Tumour involving the Cranial Bones.

—The patient was a man thirty-two years of age, and attended by Dr. Menzies and Mr. Spence. The tumour was situated at the right side of the head, and when first noticed it was not larger than a pea, but in the space of three months attained the size of an orange. Its external appearance was round and regular, owing to the dense covering of the scalp; but on manipulation it was found to be nodulated, soft, and elastic at different points. Its base was broad and undefined, and firmly attached to the skull. The patient had headache and vertigo when it first appeared, but his principal complaint was a severe pain in the right orbit and eyeball, and a peculiar difficulty which he felt in passing persons or objects placed on his left. No pain felt on pressing the tumour, nor did the pressure produce any effect on the pupils, which were sensible to the stimulus of light. Palliative measures were had recourse to, in order to relieve the pain in the orbits and headache, which, however, became more intense; and in a short time he was seized with convulsions, which succeeded each other rapidly till he died. On examining the head it was found that the surface of the tumour was closely invested by the aponeuroses and some of the muscular fibres of the occipito-frontalis and temporal muscles. On removing this covering, the external surface was seen to be lobulated, and varying in consistence at different parts, but generally soft and elastic. The tumour occupied nearly the posterior half of the right parietal bone and superior and right portion of the occipital, together with the part of the lambdoid suture between these

FATTY MATTER IN THE LUNGS.—At the las-

bones. Its extreme length measured $5\frac{1}{2}$ inches; breadth posteriorly, $5\frac{1}{2}$; and anteriorly, four inches. Internally it was limited towards the mesial line by the falx cerebri, which was much thickened. The dura mater to the right of the falx was completely destroyed by ulceration, the tumour having passed through it. Its cerebral aspect pressed upon the posterior and lateral part of the right hemisphere of the brain; the arachnoid was ulcerated, and the surface of the hemisphere was much softened, sloughy in appearance, and greatly flattened by the tumour. On making a lateral section of the hemisphere, the roof and floor of the right lateral ventricle were found closely pressed together; and on removing the posterior part of the roof, the upper surface of the right optic thalamus was found much flattened. The effects of the pressure were found to be limited to the right side of the cerebrum.

Scurvy.—"In some of the scorbutic patients," says Dr. Ritchie, one of the physicians of the Royal Infirmary, Glasgow, "admitted in the present epidemic, the infiltration of the legs by fibrinous or other effusion, and the consequent tension of the fasciæ and obstruction to the circulation, have been so great, as to suggest the occurrence of gangrene; and it is not improbable that, should we lose any by the disease, such may be one of the modes in which it will happen."

On the Presence of the Sugar of Milk in the Milk of the Carnivora.—Dumas inferred, from his experiments on the milk of the bitch, that though sugar was present in considerable proportion when the diet was vegetable, yet that the sugar disappeared entirely when the food consisted wholly of flesh. Dr. Bensch finds that this conclusion is erroneous: affirming, after careful experiments, that on long-continued exclusively animal diet the sugar does not disappear from the milk, and hence that the organism must possess the power of forming sugar of milk from the fatty or nitrogenous matter. He thinks that the difficulty of detecting sugar in the milk of dogs fed exclusively on an animal diet arises from the tendency of the phosphoric acid then present to convert the sugar of milk into uncrystallizable grape sugar, which, remaining with the extracts in a syrupy form, escapes observation.

Elaterium in Bright's Disease of the Kidney.—Rostan, in the Hôpital la Charité, has found elaterium of some advantage in this disease, though hardly coming up to the expectations he had formed of it. This he ascribes to the inefficiency of the drug to be met with at Paris, as compared with that sold in London, and he has taken steps to procure a supply of the more efficient article. The editor of the "Annales de Thérapeutique" considers elaterium so little known in France that he has transcribed in a recent number the principal part of Dr. Christison's account of this substance, as the only carefully-written article on the subject which he has met with.

Arsenic in Vinegar.—Deschamps found, on preparing pure acetic acid from wood vinegar, that the latter contained arsenic, which he ascribes to arseniferous sulphuric acid having been used in the manufacture of the pyroligneous acid. As wine vinegar is frequently strengthened with this, Chevalier was induced to examine several samples of ordinary vinegar, and found some of them to contain very perceptible quantities of arsenic.

Strangulated Hernia of the Cæcum.—Landsberg, of Breslau, relates a case occurring in a female, forty-one years of age, which proved fatal. Six months before, she had discovered a small tumour in the right groin, somewhat painful, which soon disappeared. The tumour reappeared after unusual exertion, with pain, constipation, and vomiting. On the eighth day after the attack, several stools having during this time been passed, after the use of the taxis, she had copious perspirations, painful and hurried breathing, thirst, pungent heat of surface, flushings of the face; pulse steady, and above 200; the hernial tumour, seated on the outside of the crural vessels, was

three inches long, three-lobed, elastic at the base, not tympanitic; the skin was sound, and attempts at reduction painful. The symptoms increased and the patient died. At the autopsy, a crucial incision being made over the seat of the disease, a portion of the intestine was found displaced, which was soon recognised as the cæcal appendix. It was surrounded neither by hernial sack nor serosity; it projected across the internal crural aperture above the crural vessels; towards its free extremity it had a contraction, giving an appearance as if the appendix were divided into two parts; it was thickened, black, gorged with blood, and was more than two inches in diameter. A large quantity of feculent matter issued by the crural aperture, coming from the cæcum, the posterior surface of which was gangrened. The aperture of the cæcal appendix admitted the barrel of a quill, the extremity of which passed out by a preternatural passage beyond the contraction; neither liquid nor gas issued from the cavity of the appendix.

Subperiosteal Extraction of Bones.—M. Larghi, principal surgeon of the Hospital of Kerceil, observes that the end in view being to preserve the periosteum, in order to the production of a new bone, it should be our aim in extracting the solid portion of the bone to injure the membrane as little as possible. For this purpose it should be divided no further than is necessary for the removal of the bone. The portion to be removed is either short or long. If short, it is sufficient to make a longitudinal incision parallel to the length of the portion of bone to be extracted, and reaching its surface through a muscular interspace for the sake of preserving the muscles. This incision being made, the two borders of the divided periosteum are to be separated, which is the more easy, as it is already in part separated from the bone by the gelatinous fluid secreted for this very end; and the membrane is thus to be detached all round the bone. In this manner a passage is made for a band, which, by means of a flexible needle, is brought to encircle the bone. While successive tractions are made on the bone by means of this band, the muscles inserted into the periosteum, are thrown into contraction, and act in an opposite direction over the several points of the periosteum, whence a complete separation is effected. If there be any difficulty, the injection of warm water assists. On this plan Larghi has successfully extracted the osseous part of the eighth and ninth ribs in one patient, almost the whole of the right humerus in another, a part of the right ilium in a third, the lower part of the ulna in another, and several times the first phalangeal bone of the toe.

Death of a Newborn Child from Hypertrophy of the Thyroid Gland.—A robust and full-grown infant, born in a state of asphyxia, continued to respire in an abnormal manner even after the removal of the asphyxia. A dose of squill-juice occasioned vomiting, after which the child fell asleep. On awakening, the suffocative attack was renewed, the voice being hoarse and crowing. Deglutition was also impeded, the food being swallowed with difficulty, and with evident noise. A perceptible swelling occupied the neck. On the fourth night a suffocative attack terminated life. On dissection, the thyroid gland was found engorged with blood, and composed of a very compact parenchymatous substance, and was so much enlarged as to occupy the whole anterior region of the neck, its two horns extending above the lateral parts of the thyroid bone; its lateral borders reaching beyond the anterior margins of the sterno-mastoid muscles; the upper concave edge covering the larynx, its lower the upper part of the sternal manubrium. Behind the thyroid gland there were seen two thick muscles surrounding the windpipe and throat throughout. The most considerable stricture of the trachea was at its lower part, while the rima glottidis was perfectly normal. At the bifurcation of the trachea a great quantity of dirty milk-like mucus was met with. The thymus was less developed; both lungs of normal appearance, with the exception of the top, which exhibited several more compact, somewhat liver

like, dark red spots. The heart was deep red, and, as well as the pericardium, was engorged with venous blood. In the pericardium there was about a spoonful of yellow serum; the valve of the foramen ovale was not yet quite closed. There are two diseases which might have been confounded with that just described—*asthma stridulum*, and croup. These differ, however, in many points: the former, by its more tardy appearance, the non-permanency of the dyspnoea, the tetanic spasm, and complete interruption of the respiratory process at the close of life; the latter, by the normal deglutition, and, in common with the former, by its more tardy appearance.

Ligature of the Penis for Nocturnal Emissions.—M. Teisser relates the case of a young man, who, having been for a length of time treated unsuccessfully for nocturnal emissions, conceived the idea of tying a ribbon round the penis at night. The constriction produced during erection awoke the patient, who, by getting up, and emptying the bladder, was able to pass the night comfortably.

Tincture of Aconite in Rheumatism.—M. Magand gives the preference to the tincture, above the other preparations of aconite, in the treatment of rheumatism. He has tried its efficacy in several cases. The first was a young lady affected with occasional pains in the left arm, induced by atmospheric vicissitudes, and continued for four or five days in succession. These pains were completely removed by the administration of six drops of the tincture. The second was an old man subject to darting pains in the face and limbs. Being a robust man, blood was taken from the arm in the last attack, and six drops of the tincture were given every night and morning; the pains diminished, and disappeared in three days. The third was a person affected with chronic rheumatism in the lower limbs, the wrists, and the loins. The tincture was given in doses of six drops, gradually increased to thirty, three times a day, with perfect success.

Incision of the Os Uteri in Labour.—M. Nichet regards the above operation as warranted in puerperal convulsions, in which the extraction of the fetus is deemed necessary when serious hemorrhage appears at the close of pregnancy, and the cervix remains undilatable; in contraction of the pelvis, when it has been ascertained by measurement that the application of the forceps will be necessary, and the neck does not readily dilate; and when the head is separated from the trunk, and remains within the womb, the rigidity of the neck not allowing of the introduction of the hand.

Wound of the Scrotum, with Hernia of the Testicle.—A young man fell from a tree upon a stake fixed below, which penetrated the scrotum, and tore it into two unequal parts. M. Ollivier, on his arrival, found both testes completely exposed, and the injured scrotum gangrenous in several points. The injury occupied its entire length from the perineum to the root of the penis. The patient was bled, strictly dieted, and purged. The parts being well sponged, the testicles were replaced, being kept in situ by ligatures. Next day a large portion of scrotum sloughed away, and the left testicle was again uncovered; and, from engorgement, it was found impossible to form a scrotal investment for it. Under these circumstances, the part was dressed with simple dressing, and in the course of two months the lost portion of the scrotum was entirely restored, the testicle becoming adherent.

Syrup of Hydrocyanic Acid.—Dr. Reich prepares it as follows:—Take of sweet almonds two ounces; immerse them for the space of a night in cold distilled water, and in the morning remove the skin by pressure of the finger and thumb; then pound the almonds in a deep mortar, adding two ounces of the purest sugar. Pound together in a mortar, either of porcelain or marble; then by degrees add distilled water two ounces, and strain with the application of slight force. To this emulsion add sugar of the purest kind two ounces, and promote solution by mixture alone, heat being avoided. To four ounces of this

syrup add seventeen grains of amygdaline, and rub together in a porcelain mortar. Much of the syrup need not be kept ready prepared, as its extemporaneous formation is so easy. An ounce contains a quarter of a grain of real prussic acid.

Jahuria Neonatorum.—A child died the thirteenth day after birth, and for the last five passed, while under the care of Dr. Bednar, no urine. It is not known if he passed any on the previous days. Dissection showed that the caput gallinaginis, instead of passing into a prominence, ended in two branches, which again divided into a great number of little folds, and was here branched at its anterior extremity into two mucus valves running along the walls of the urethra, from behind, downwards and forwards, towards the middle space, where they united together. The two crescentic valves, with their concavity looking towards the bladder, included between their combined terminations a very narrow fissure, running necessarily from behind forwards. From the structure it is evident that, whenever the bladder contracted on the urine, the concavity of the valves became filled with it, and the fissure between them being completed by their distention, not a drop could issue beyond. It was easy to pass a thick probe from the anterior part of the urethra into the bladder, but when the probe was passed from the bladder it was impossible to reach the urethra without the assistance of the eye, the probe being otherwise continually thrown back by the valves. The urinary bladder was hypertrophied, its usual thickness being trebled, the thickening being principally in the muscular coat. On the inner surface of the bladder there were an incipient tubercular tissue, some little previous dilatations, and a great sack with a sphincter-like opening at the termination of the left ureter. The remaining portion was dilated and thickened; the renal substance was atrophied.

Iodide of Potassium in Hemiplegia.—The patient was a female, in the Hôpital la Charité, under M. Briquet. The disease had existed for two years, before which she enjoyed good health. When admitted, there were complete loss of feeling over the whole of one side, and, to a considerable extent, loss of motion; the attack had been preceded for a few days by vertigo, and by convulsive movements of the face. The diagnosis was that the disease depended on a syphilitic tumour (exostosis or periostosis) at the base of osium, and the patient was put under full doses of iodide of potassium. The treatment was continued for two months, in doses increased from ten to eighteen grains a day, with the most striking success. There is now hardly any remains of the disease, except that the integuments over the great pectoral and in the clavicular region of the left side are still insensible, and the tongue still turns a little to the right when put out. The same treatment is still continued, with progressive improvement. The patient denies that she ever had syphilis.

Spontaneous Evolution.—Dr. Keiller related to the Edinburgh Obstetrical Society the case of a woman whom he attended during labour, and to whom he was not summoned till the case had assumed the following aspect:—The liquor amnii discharged, a large swollen arm occupying the passages, the os uteri firmly grasping the obtruded shoulder, and the uterine contractions unusually violent and continuous. Repeated attempts to insinuate the hand, to effect turning, failed; and notwithstanding the free use of opium, the uterine contractions continued, when, during a violent pain, the arm was suddenly withdrawn, and the feet and body almost simultaneously expelled—a rapid and complete evolution having spontaneously occurred. The child was dead, but the mother made a good recovery.

Belladonna in Orchitis.—Dr. Philippe, chief surgeon to the Military Hospital at Bordeaux, uses an ointment, consisting of one part of the extract of belladonna to three of lard, for the cure of inflammation of the testicle, when arising from direct injury, or as the result of urthritis. It is found to be most useful when the acute inflammatory symptoms have been previously sub-

dued, or in cases where induration and thickening of the epididymis remain after other treatment. Half a drachm of the ointment is rubbed into the scrotum twice daily, the incision being continued for five minutes each time. The mean period of cure was five days, in thirty cases thus treated. The ointment has been also used with great success in the treatment of buboes.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsman or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein Carfrae, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

A Poor-law Medical Officer.—It is evident that the services of the profession are not properly estimated, or remunerated. No officers connected with unions have such niggardly sums doled out to them as the surgeons. As the lives of paupers appear to be of little value in the eyes of certain parties, they allow but pitiable sums for attendance and medicines in their illness. If the members of the profession would only unite to resist every act of injustice towards them, better remuneration for their services would inevitably follow.

A Dublin Surgeon.—The reply of the Lord Lieutenant exhibits the apathy of the authorities to increase the rate of pay. The conflict having commenced, we trust that no medical man will be found to betray the interests of his profession into the hands of its opponents. Patience and perseverance will accomplish wonders.

A Student. 1. The matriculation examination is just over. 2. The information required may be obtained from Taylor and Walton, booksellers, Gower-street. 3. University College is not the University any more than King's; there are other colleges, also, in different parts of the kingdom connected with the University.

A Regular Reader.—The information was given in the Medical Times a fortnight ago; the appointment is open to all qualified practitioners, and is sought after not so much on account of the salary connected with it, as the honour.

M. D., Assistant-Surgeon of the Royal Navy.—We are much obliged for the compliment; our desire is to see the whole professional body duly honoured and rewarded, and we shall not cease using our best efforts to accomplish this. We thank our correspondent for his information, and shall not fail to make use of it in a short time.

Mr. Joseph Orton.—The amount cannot be recovered, and the expenses incurred must be placed among the items of a bad debt.

M.R.C.S. and L.A.S.—A gentleman who possesses only the Apothecaries' license is a duly-qualified practitioner; there is scarcely one who, with a single qualification, is not also educated in the art and science of surgery. The Council of the College of Surgeons has done a great injury to their diploma by the statements which they have made in reference to it from time to time; and the consequence is that many now refuse to pass an examination for it, though, by not possessing it, they are placed under the disadvantage of not being eligible for Government situations.

An M. D., of St. Andrew's.—We have no doubt that the examination is one of a searching nature; the number of rejections is not a true criterion of the amount of information required to possess the diploma sought after. There is a good deal of caprice in examiners as well as others. The fate of Mason Good, and John Armstrong, shows that the rejected are not always the least informed of the candidates.

Dr. Orpen, Birkenhead.—The communication has been received.

H. M. L.—Midwifery is a part of professional duties undertaken by the general practitioner. The pure surgeon repudiates it. We cannot under-

stand what a person is, with the Apothecaries' license, if he is not a general practitioner. Druggists now occupy the place of the apothecaries of former times.

Mr. T. Mayhew.—The steam jet has been employed with success in ventilating buildings. We believe that this method is used for ventilating the new House of Lords.

S. S., Maidstone.—We cannot, without considerable alteration, insert the paper, and then it must be authenticated.

A Bachelor.—Oxford and Cambridge, as schools of medicine, are below mediocrity. Downing, in Cambridge, is the principal college for medical students. Addenbrook Hospital, we think, contains about eighty beds.

A Surgeon.—The information can best be obtained of Mr. Balfour, at the College of Surgeons. It is not within our province to undertake the inquiry.

Georgius, Hoxton.—At the Polytechnic Institution there are exhibited experiments on electricity produced by the action of steam.

Mr. S. Alport.—Chemical analysis, to be despatched and successfully practised, should be frequently performed. The law allows only one guinea for a post-mortem examination, at a coroner's inquest, if an analysis is connected with it. This is another proof of the liberality of the Government to the profession—much time, trouble, and expense being often required to bring to light facts which are necessary to be known in order to the conviction of the guilty.

T. S., Greenwich.—We are sorry for our correspondent, and would recommend him by all means to observe the strictest temperance; at the same time to consult some medical practitioner in the neighbourhood, as we make it an invariable rule never to prescribe through our columns.

Discipulus.—For beginners, Comstock's, published by Simpkin, Marshall, and Co.

Mr. T. Walker, Maiden-lane.—King's College Hospital.

W. W., Leominster.—Danson, published by Hughes, St. Martin's-lane.

Civis Academicus Edinburgensis, Manchester.—We would advise our correspondent to procure the license. With the education which he possesses, we should think he would not fail to pass an examination without "procuring the most approved textbooks now in use amongst embryonic apothecaries."

Truthseeker says that "A paragraph in your correspondence of the 5th of June has just met my eye, in which 'Truthseeker' is stated to have recanted the opinions conveyed in the letter alluded to. May I request you to compare the handwriting, and you will easily discover that the misnamed truthseeker of the 5th of June is some unprincipled person."

Letters and communications have also been received from Mr. T. Mayhew; S. S., Maidstone; A. Bachelor; A Surgeon; Georgius, Hoxton; Mr. S. Alport; T. S., Greenwich; Discipulus; Mr. T. Walker, Maiden-lane; W. W., Leominster; An M.D. of St. Andrew's; M.R.C.S. and L.A.S.; Mr. Joseph Orton, M.D., Assistant-Surgeon of the Royal Navy; A Regular Reader; A Student; A Dublin Surgeon; A Poor-law Medical Officer; Truthseeker; H. M. L.; Civis Academicus Edinburgensis, Manchester; Dr. Orpen, Birkenhead.

THE MEDICAL TIMES.

SATURDAY, JULY 24, 1847.

THE ARMY AND NAVY MEDICAL SERVICES.

THERE are officers in the service of their country whose duties are as honourable and useful as any upon whom the highest rewards are bestowed, but who, from peculiar circumstances, are doomed to experience public neglect. The cause

of this injustice is, without doubt, oftentimes to be attributed to the force of habit, by which a science, however beneficial, whose advantages are recently developed, fails to make that impression on the public which one that is ancient and useful does. War has been the employment of men from remote ages, and those who have proved successful in battle, through their skill and courage, have been, for thousands of generations, applauded and honoured. The names of heroes live on the page of history, and even now their exploits are more intensely admired than the actions of those who gave to the world a knowledge of the sciences which are the fountains of prosperity and happiness. We cannot wonder that barbarous nations should consider strength, courage, and success, a trinity of perfections entitled to receive supreme veneration and the most costly gifts; but it is not for nations advanced in civilization to view those attributes as alone worthy of entire regard.

There are benefactors as useful to the commonwealth as military chieftains; and it is the duty of an intelligent people to break through habits engendered by an antiquated barbarism, and to reward every man according to his deserts. The blessings which medical science confers upon mankind are as great and permanent as military conquests, and the successful cultivators of it are as much entitled to reward. There is no class of society—no branch of the public service—that is not dependent upon it for occasional help; and yet, up to the present time, the members of the medical profession have little cause for thankfulness, either to the Government or to the people, on account of what they have done for them. Both have given but sorry rewards to medical practitioners for the benefits which they have been instrumental in conferring upon the community, and both have evinced a reprehensible tardiness in recognising their claims to honorary distinctions.

True it is that, as a science, medicine dates its origin from a period remote in the history of the world; but it was doomed for upwards of twelve centuries to experience a living death, through the baneful influence of error and superstition. Its ravivification has taken place in these modern times, and so strange are the demands which it now makes, that, though their justice is tacitly acknowledged, its requirements have been almost disregarded. The cultivators of medical science have yet to overcome the apathy of governments, and to win their way to public honours; and the success of their cause will be in exact proportion to the advance of civilization, affording at the same time no better criterion by which to judge of its progress amongst a people. In our own country the Government can no longer allow their medical officers to remain in a position of contemptible mediocrity, without powerful remonstrances against the injustice. The claims of the army surgeons to the same honours which have been awarded to the heroes of the Peninsula, with whom they served, have been advocated not only by the medical and general press, but by military officers in the British Parliament. If the advocates have not now obtained for their clients all the honours to which they are entitled, they have at least taught the Government a lesson that they cannot much longer withhold from their medical servants that which is their due.

And not only is justice asked for army surgeons, but also for navy assistants. What is demanded for them is the treatment of gentle-

men and officers. It may be all very well for the midshipmen to undergo an incubation in the gunroom, in order that they may eventually come forth full-fledged officers of her Majesty's navy; but the assistant-surgeon is something more than an embryo chicken. He wants none of this marine incubation to make him a gentleman, a scholar, and an officer; the attributes of each he possessed the first moment he set his foot on the quarter-deck, or his visit there would be very unwelcome and very brief. He does not go into the navy to learn the first principles of his profession, as his messmates do; already is he in the possession of a diploma which not only authorizes him to practise the healing art, but is a guarantee that he has received an amount of instruction in the academies of medicine calculated to fit him for an efficient discharge of his important engagements. The Government can now offer no valid excuse for consigning him to their naval hades, where he has to remain an indefinite period before he is considered fit for the society of the regions above. What else is this but a cruel purgatory for body and spirit, out of which the earnest entreaties of his brethren alone can deliver him.

In times gone by, when the Government was pressed for the want of medical officers, and when oftentimes it was compelled to accept the services of those whose education had been defective, there was some show of reason for placing the assistant-surgeon with mates and midshipmen, and volunteers and clerks. Now, my Lords of the Admiralty can pick and choose from amongst graduates of universities and members of colleges; and thus, having servants with higher collegiate qualifications, they should certainly give them better treatment. Everything connected with the gunroom marks its inferiority. There the surgeon has for companions the mates, the midshipmen, the second master and his assistants, volunteers, and clerks—naval "gentlemen" by courtesy, but wanting a commission to make them officers. These mess together under the wardroom, and close to the cockpit—and, still further to mark their inferiority, their meals are served at the same time as the ship's company generally, at the hour of noon, and the exciting strains of the drum and fife playing the tune of "The Roast Beef of Old England," are not permitted to summon them to their repast. Now, we should like to know the reason why the members of our profession, serving in the capacity of assistants on board her Majesty's ships, are thus to be treated? Why the Government should compel them to companion with boys during the day, and to swing in a hammock by night?—why no opportunities should be afforded them of cultivating their professional studies without the danger of interruption from thoughtless and boisterous youths? To allow such a state of things any longer to exist would be derogatory to the whole profession.

The gentlemen whose cause we now plead are our representatives in a particular department of her Majesty's service; and, if we permit them further to be quietly insulted, it will show not only a spirit unbecoming enlightened and honourable minds, but will assuredly expose the whole medical community to anything but respectable treatment from the members of the Executive. Let the surgeons in the army remember the recent slight put upon them, which should be a powerful stimulus to urge them to untiring exertions for their brethren

acting as subordinates in the navy. Let the medical officers in this service, who enjoy the privileges of the wardroom, call to mind their former degradation, and endeavour to avenge the insult offered to themselves by seeking to rescue their assistants from their present degrading bondage. Let the members of the profession, who are civilians under the control of the Government, remember the wretched remuneration which they receive; and, in order to the removal of their own yoke, assist in taking it from the necks of others. Let the general practitioners of the empire treasure up in their bosoms the efforts that have been employed to make them bite the dust, and let them show that they will never have the foot upon their own necks, by coming to the rescue of those who are already prostrate. Let the assistant-surgeons themselves exhibit a regard for their own high calling, by unceasingly struggling to obtain that honourable position to which they are entitled, and which they most assuredly will secure, if they resolutely seek it. While the members of the profession generally come forward to their help, it is expected that no supineness will be manifested by those whose cause is advocated. We shall then speedily see them emancipated from the companionship of those embryo naval officers who, while occupants of the gunroom, "receive for half-pay three farthings per annum, payable quarterly, to puzzle the clerks."

THE IRISH MEDICAL PROTEST.

FEVER is, at the present time, raging in Ireland to a fearful extent cutting down, on the right hand and on the left, the high and low, the rich and poor. The hospitals are full, the number of sheds erected are inadequate to contain all the victims of the direful pestilence, and multitudes are lying about the streets, unable to obtain a bed upon which they may lie down and die. At this terrible crisis, the Government has solicited the aid of the medical profession of that country, that their skill may be employed in combating the frightful ravages of disease, and in alleviating the sufferings of those who have the misfortune to be afflicted. The result is, that a misunderstanding has occurred between the members of the profession and the Government, which has led to the presentation of a manifesto to the Lord Lieutenant, signed by 1106 physicians and surgeons. To this medical representation we beg to direct especial attention, as it brings forward the points at issue between the two parties, and enables us to judge of the liberality of the Government in regarding those who are called to peril their lives in attending upon the sick.

The representation commences with the declaration "that the zeal and efficiency with which the medical profession of Ireland has discharged their duties, together with their importance to the public welfare, eminently entitle that profession to the protection and support of the Government."

It is very satisfactory to observe the spirited and dignified commencement of the manifesto. It utters truths which the Government is dared to deny if it can. Throughout the United Kingdoms the medical profession is renowned as a body for the discharge of their duties both zealously and efficiently. The members set their hearts upon their work, which enables them to brave danger, and, their minds being well stored with learning and experience, the various accidents and diseases which they are called to attend are treated in accordance with the principles

of true science. This being the case, they are certainly entitled to the protection and support of the Government. No country can be prosperous or happy without health; and we say deliberately that there is no body of men throughout Great Britain and Ireland who have done so much good in promoting the physical and general welfare of the people, as medical practitioners. They have indirectly secured the enactment of good laws, have been the means of beautifying and rendering salubrious our large cities, and have banished a vast amount of disease from the cottages of the poor. Even now they are the principal champions of sanitary reform, and are backing the Government, heart and hand, against the attacks of inhuman monopolists. If these things do not entitle them to the protection and support of the Executive, then are we at a loss to conjecture what will. But we shall see what protection and support they have received. The statistical returns, for upwards of twenty-five years, exhibit a fearful mortality from fever among the medical men of Ireland; and no class of the community has been exposed to more dangers, or has exhibited more readiness and courage to enter into them. Why, the courage of a military man is nothing to be compared to that which is required from the physician. The roar of artillery and the exciting strains of music, with all the pomp and circumstance of war, stir up the one to a frenzied desire for glory; while the other beholds the ghastly countenance, hears the groans of the sorrowful and dying, scents the foul and pestilential air which introduces into the vital current the germs of disease, that may, perchance, speedily prostrate him in death. And what are the rewards of Government? Does it adopt the same mode of proceeding towards the medical as the military or other professions? There are good livings and bishoprics for the clergy, chancellorships and other nice berths for the lawyer, coronets and costly gifts for the soldier; but, as the manifesto declares, "The members of the medical profession have reason to complain that they sustain hardship and injustice when employed in the public service, in some instances being denied any remuneration whatever for such services, or are constrained to accept sums utterly disproportionate to the duties they are compelled to discharge." All the medical men of the empire are thus rewarded—their lives and skill, as we shall presently see, being estimated at five shillings per day in Ireland, and about the same value put upon them throughout England and Wales. "We strongly protest," say the memorialists, "against the amount of remuneration offered by the Board of Health to physicians and surgeons for attending fever hospitals during the present epidemic; as, in some instances, five shillings per day have been offered for the discharge of that onerous, responsible, and dangerous duty. Protest! yes; and we earnestly hope that they will continue to do so, and that the medical practitioners on this side of the water will, for their own sakes, back their efforts to raise themselves from the degrading position in which certain public functionaries would place them. Now, we should like that the gentlemen who entertain such liberal views of the value of medical life and skill should be compelled for an hour each day to accompany one or other of the medical attendants, whom they would thus pay, in order that their eyes may be saluted with the same sights, and their noses with the same scents. Only one hour, we have no doubt, would make

them very humbly cry *peccavi*, and would lead them cheerfully to award to the medical attendants four times the amount they now do.

We are aware that the members of the profession will have to encounter difficulties of no ordinary kind, in endeavouring to obtain a proper reward for their services. Their philanthropy will be called in question, and they will be accused of a sordid love of gold. They must be prepared to brave unjust insinuations, and to maintain perseveringly their right to fair remuneration. Their knowledge has been purchased at no mean sum, and surely its exercise ought to be paid for in a just proportion. While we thus speak, we are aware that no pecuniary remuneration would be an equivalent in many instances for the services rendered by the profession to the public: it ought not, therefore, to be treated either disrespectfully or unjustly.

We are glad to see that our Irish brethren are resolved not to be insulted, and tamely submit. There is pluck and bottom about them, which, no doubt, have put the members of the Government into a little fluster; and the English members of the profession are equally prepared to assert and maintain their rights. We have been oppressed because we have been divided, and it only requires union to obtain respect, privileges, and rewards. We have been long enough in the school of adversity to teach us this, and there are signs which indicate the arrival of better days. Unity and resolution will make the Government and the public value medical services more, and reward them better.

THE VALUE OF THE APOTHECARIES' LICENSE.

[To the Editor of the Medical Times.]

SIR,—Your remarks in last week's journal on the uselessness of the license of Apothecaries' Hall, as a protection to its members, is most strikingly exemplified in this neighbourhood, where there are two unqualified practitioners to one qualified. Repeated remonstrances have been made to the society, but with no result, as the evil is on the increase; and the chemists are now sending out labels, and giving out to the world that they are qualified to practise; and, to delude the ignorant, place the Pharmaceutical certificate, handsomely framed, in some conspicuous part of their shop, and state it to be a license to practise. This has been done to a great extent lately, in the belief that Wakley's abortion would become the law, which happily is not yet the case, and I with many others trust will not be, as it would to some extent countenance their audacious conduct.

Pray, Sir, urge the committee of the National Society to take the matter up, as I know many will secede from it if they do not. They profess to assist their members in checking illegal practice, but they have done nothing; yet they would treble their numbers if they showed a disposition to carry out only that one promise. I have to-day conversed with four members, who I see have subscribed their guinea, and they state their firm determination not to continue subscribers, unless a distinct pledge be held out by the council to assist in carrying out the penal clause of the Apothecaries' Act; while, at the same time, they would willingly double the amount if something be done to assist in extirpating the horde of empirics that practise in this neighbourhood.

As a constant subscriber to your valuable publication, I thank you for the efforts you have made, and trust you will persevere in the course. At the same time, much remains to be done, and, while some of us are calling out for a collegiate establishment, the pirates are destroying the very means which would enable us to give respect and dignity to it. It is the fable of the "Dog and Shadow" with a vengeance; therefore, urge by all means the protection of the members,

and then a phalanx will be formed that will put a new face upon matters, and we shall have our rights in spite of college traitors and pettifogging politicians.

Yours most respectfully, in haste,
A GENERAL PRACTITIONER WITH TWO TAILS.
Bethnal-green, July 19.

COLLEGE OF SURGEONS.
PETITION OF GEORGE JAMES GUTHRIE.
THE HUMBLE PETITION OF GEORGE JAMES GUTHRIE, ONE OF THE COUNCIL AND LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND,
Sheweth—

That your petitioner having petitioned your honourable House, on two different occasions, against any medical legislation taking place until inquiry had been made into the nature of the new charter lately granted to the College of Surgeons, and which inquiry he considers necessary for the due administration of justice, naturally, and he hopes not unreasonably, expected to be examined by the committee appointed by your honourable House "to inquire into the registration of legally-qualified practitioners of medicine and surgery, and into the laws and charters relating to the practice of medicine and surgery in Great Britain and Ireland," in preference to others who had not so petitioned.

Your petitioner, on hearing that your committee had only summoned before them such gentlemen as were known to support the parts of the charter of the College of Surgeons which he had condemned as unjust towards the profession at large, addressed the following letter to the chairman:—

(Copy.)

4, Berkeley-street, Berkeley-square,
July 9, 1847.

SIR,—I had the honour of addressing a letter to you on the 10th ultimo, requesting to be examined before the Committee on Medical Registration, over which you preside, against any legislation taking place until the charter lately granted to the College of Surgeons of England should be inquired into, being under the belief that the evidence thus given would demonstrate the defective principles on which the bills introduced into Parliament by Sir James Graham and Mr. Wakley are founded.

My letter was written from my being aware that the president and council of the College had very honourably abstained from making any application whatever, either directly or indirectly, to you or any other member of your committee, for the examination of any one of their members; and I should not presume to draw attention to the fact of two junior members of the council having been selected for examination, in preference to Mr. Kento, Mr. Vincent, and myself, the three seniors, if it were not that, if the approaching termination of the session should bring the labours of the committee to a close, the evidence taken will embrace and bring before the public the views of only one party in the row. If the committee should be unable to give me opportunity of proving the very illiberal and unjust nature of the charter and the by-laws emanating from it, and which nine-tenths of the members of the College condemn, I then pray the committee will be pleased to place this letter on their minutes, in order that those officers of the public service, members of the College, who have requested me to maintain those just and vested rights and interests which have been so improperly violated, may at least have the satisfaction of knowing that I have made every effort in my power to obtain for them a public hearing.

(Signed) G. J. GUTHRIE.
Your petitioner humbly prays, that as your committee have not been able to hear him, your honourable House will give him an opportunity of proving that illiberality and injustice with which nearly the whole of the members of the College of Surgeons have been treated, and of which so many have complained by petition to your honourable House.
July 19, 1847. G. J. GUTHRIE.

INQUEST ON MISS SOPHIA DALLETT,
AT PUTNEY.

It is right to premise that this inquest was called at the instigation of Dr. Cormack, the attendant of the deceased (the daughter of a most respectable inhabitant of Putney), as there had been much obscurity in the case, not only to justify his own treatment, but even to defend it from a supposition, which it seems had got abroad (by no means an unusual circumstance in these cases), that it had proved more fatal than the disease.

The important facts elicited at the first meeting of the jury were, of course, more fully detailed at the adjourned investigation, when, in obedience to the coroner's warrant, a *post-mortem* examination had been made. This second inquiry took place at ten A.M., on Wednesday the 14th instant, before Mr. Carter, the coroner, and a most respectable jury, at the Rising Sun Tavern, in the town. The medical men present were Dr. Cormack, Dr. Robert Willis, Dr. Wane and Mr. Shilitoe—the two latter having been directed by the coroner to make the examination.—and Mr. Bushell, of Kennington, who had been present at the *post-mortem* examination (as we understood) at the request of the friends. Mr. Kempster, the solicitor to the family, was likewise present during the investigation.

On the resumption of the inquiry, Dr. Cormack's former evidence was read over to him by the coroner: it was to the effect that he had been called to attend Miss Sophia Dallett, for the first time, on Tuesday the 6th instant, at ten in the forenoon, when he found her complaining of severe abdominal pain and distressing retching; for which he ordered her a mixture containing a small quantity of the muscate of morphia, one half to be taken immediately, the other half in two hours' time; and subsequently a mixture containing creasote to control the sickness, one half to be taken immediately, the other a short time after, should the sickness not be checked; that he was again sent for about four in the afternoon, when, finding the symptoms not materially relieved, he ordered three pills of pulv. opii and ext. hyoseyami, one to be taken every hour, and a liniment composed of sp. terebinth. lin., sesquicarb. ammoniac, et tinct. opii; to be applied to the abdomen; that he was peremptorily summoned about four o'clock on the following morning, when he found his patient in a state which he conceived to be that of narcotism—she being insensible to questions unless very loudly put, the most utter prostration, with a scarcely appreciable pulse; conceiving this to be the effect of the opiate treatment, both external and internal (although but 3jss. had been used in the former way, and not more than half a grain administered in the latter), he emptied the stomach by an emetic of sulphate and zinc, and then endeavoured to bring about reaction by means of brandy and wine; that he staid with his patient upwards of three hours, causing her to pace her apartment, when, finding his efforts were altogether unavailing, and that he was himself becoming exhausted, he sent for his friend, Dr. Wane, to relieve him—shortly after the arrival of whom, between eight and nine o'clock, the young lady expired.

These minutes having been confirmed, Dr. Cormack now stated, in answer to questions put to him, that he was a graduate of the University of Edinburgh, and a Fellow of the Royal College of Physicians of Edinburgh; that he had been in practice upwards of twelve years; that he now considered that the unfortunate subject of the investigation was not labouring under narcotism, as he was at first induced to suppose, but that she was suffering from an attack of fever, to which the symptoms described were owing; that he had had great experience in the treatment of fever, in consequence of his connection for a long period with the Fever Hospital of Edinburgh; that fever was constantly attended by enteric mischief, in proof of which he read a quotation from a

work by Dr. Watson, of King's College, London; considered that his treatment had been careful and judicious; as a *post-mortem* examination had been made, would refer the coroner and jury to the gentlemen who had been deputed to make that examination, for an opinion of what had proved fatal to the patient, founded on the particulars thereby disclosed.

Emma Peto examined: Is servant to Mr. Dallett; remembers being sent for Dr. Cormack, about ten on Tuesday morning, and subsequently to his surgery for some medicine, on which occasion she received two mixtures from the assistant; was sent again about four P.M. for Dr. Cormack, and after his visit for the medicine, when she got from the assistant a vial and a box of pills, which were compounded in her presence. Took these home and gave them to Miss Dallett (the elder sister of the patient), who, finding that the pills were directed to be taken one every night instead of one every hour, as Dr. Cormack had mentioned, sent her back with them to mention the circumstance, when the assistant remarked that the error was merely in the direction, which having altered, he returned the box. The assistant weighed but one of the articles he used for the pills; is sure he did not weigh more.

Henry Hicks was now called in, and examined: Is visiting and dispensing assistant to Dr. Cormack; has been with him about six weeks; is fifty-four years of age; has had great experience in the compounding of medicine; is a member of the profession, qualified by being in practice before the act of 1815; recollects making up the following prescriptions:—

R. Sol. mur. morphia, grt. xij.; tinct. auran-
tii, 3j.; mistura camphoræ, 3xij. M. half to
be taken immediately, the other in two hours;
likewise, at the same time, a mixture composed
of creasote, a half of which was directed to be
taken if the vomiting continued; and after the
second visit of Dr. Cormack the following lini-
ment and pills:—

R. Sp. terebinth. lin., sesquicarb. ammoniac,
aa. ʒv.; tinct. opii, ʒij. M. to be applied to
the abdomen.

R. Pulv. opii, ext. hyoseyami, an. gr. ʒ;
mucilag. acaciæ, q. s. fit. pil. iij., one to be taken
every hour.

Can swear that these prescriptions were all accurately compounded; that he weighed both articles; omitted the mucilage, the extract being sufficiently soft to make the pills; is confident that there was no error whatever in the dispensing of the pills.

Coroner: How came it, then, that the servant was sent back with them?

Witness: Oh, yes, I believe that I did misdirect them in the hurry of business, but in other particulars they were perfectly correct.

Mr. Bushell: Are you confident that you did not commit the error of supposing that the ingredients ordered for the three pills were to constitute one, and that you did not act upon this supposition?

Witness: I am quite confident that I did not.

Mr. Bushell: You say that you weighed the two articles; pray how did you weigh the extract, as it was soft enough to make the pills without the aid of mucilage, that it did not stick to the scale?

Witness: I weighed it upon a piece of paper.

Mr. Bushell remarked that it was strange this had not attracted the notice of the servant. He then inquired the size of the pills.

Witness replied that they were about the size of a blanket-pin's head.

Daniel Wane was then called: Is a medical doctor, resident in Putney; has been in practice now several years, prior to which, from his official connection with several large institutions, had extensive opportunities of acquiring a knowledge of disease; was sent for by Dr. Cormack, to relieve him in his attendance on Miss Dallett, about seven o'clock A.M.; found her sitting on a chair on the landing, outside her room-door, perfectly insensible; considered her in great danger; conceived, with Dr. Cormack, that she

was labouring under narcotism from the opiate administered and absorbed; gave another sulphate of zinc emetic, which, however, produced no alteration of symptoms; applied sinapism over the stomach; administered strong coffee, irritated the fauces with a feather, put the hands and feet into warm water, and intended to use the stomach-pump in twenty minutes after these means, if there were no improvement; about this time, however, the patient expired. Thought at the time, and thinks still, the treatment judicious for the symptoms under the supposition to which they naturally gave rise; on walking with Dr. Cormack, after the decease, he expressed an opinion that the disease had been that of cholera; the treatment would not have been the same had the symptoms been considered to result from morbid and not medicinal action. Dr. Shilitoe was subsequently sent to his assistance by Dr. Cormack; made an inspection of the body in company with Mr. Shilitoe, by the coroner's order, at which the following report was drawn up and signed, as well as by themselves, by Dr. Robert Willis, of Barnes; Dr. Shilitoe, Dr. Cormack, and Mr. Bushell, which witnesses now read:—

POST-MORTEM EXAMINATION OF SOPHIA DALLETT,
MADE JULY 10, 1847, HALF-PAST THREE P.M.

External Appearances.—Integuments of the abdomen of a somewhat greenish hue, from decomposition; there was some lividity of the back, arms, neck, lips, and trunk; the articulations of the upper extremities were flaccid; there was rigidity of the trunk and lower extremities; no emaciation existed; the general habit was slender; the mammae were well developed; there was hair on the pubes and under the axillæ.

Head.—The vessels of the dura mater were turgid, and, when cut, there was free effusion of blood; there was very great congestion of the vessels of the pia mater; a very slight degree of subarachnoid effusion was observed; the consistence of the encephalon was tolerably firm. On dividing the vessels at the base of the brain, there was a copious flow of blood, with fetid air; numerous bloody points were seen on making a section of both hemispheres; there was less than the usual quantity of fluid in the lateral ventricles, and this effusion was stained with blood; the choroid plexus and internal surface of the ventricles were congested. The base of the brain was next examined: there was general congestion of the vessels; the encephalon was very carefully examined in every part, and it was found not to present any further appearance of disease.

Chest.—On opening the left pleural cavity, about two ounces of bloody serum were seen; there was no fluid in the right cavity; general adhesions of old standing existed between the pleura pulmonalis and pleura costalis of the right side; cadaveric congestion of the posterior part of both lungs existed; there was very little serum in the pericardium, which was healthy.

Abdomen.—The intestines, generally, were distended with gas; the small intestines in various parts were of a bright red and blotched appearance, which appearance presented itself in a more marked degree when the intestines were raised; adhesions from bands of very recently effused coagulable lymph were observed, and in one part the intestine was coated with coagulable lymph; a small quantity of turbid, bloody fluid was found in the lower part of the abdominal cavity; the redness of the small intestines was more remarkable towards the lower portions. On slitting open the small intestine, a very marked, congested, red state was noticed on many parts of the mucous membrane—the result or evidence of inflammation. The glands of Peyer and the solitary glands were of unusual size and distinctness. This unnatural state increased as the great intestine was approached, so that the mucous membrane of the upper extremity of the small intestine, to the extent of ten or twelve inches, appeared thickened; this portion of intestine was also the seat of several distinct ulcerations. The mucous membrane of the ileo-cæcal valve was red, and much thickened; the mucous membrane of the large intestines (through

THE MEDICAL TIMES.

was in a state indicating congestion of the peritoneal coat of the intestines; the liver was natural; the gall-bladder was distended with bile; the spleen was larger than natural; the kidneys were healthy; the stomach, externally, was of a reddish colour, and internally of the same hue, partly owing to congestion with blood, and partly dependent on (sanguineous?) staining. The stomach contained about an ounce of fluid. The intestines contained little but air.

From what the post-mortem examination revealed, witness is now of opinion that the symptoms preceding death were not those of narcotism, but of cerebral derangement or fever, which, together with enteritis and peritonitis, destroyed the patient; considers the plan of treatment adopted by Dr. Cormack the best that could have been devised.

Mr. Bushell inquired of witness if exhaustion did not proceed rapidly under the treatment he had personally witnessed? Witness replied, Not more so than was to be expected.

Mr. Bushell: Pray are cerebral congestion and peritonitis frequently coexistent?

Witness: Decidedly.

Mr. Bushell: From the post-mortem appearances, was there not enough to produce speedy death, in all probability, whatever treatment had been adopted? I ask this in fairness to Dr. Cormack.

Witness: I really cannot say.

Mr. Shillitoe and Dr. Willis confirmed the opinion of the last witness, both indubitably expressing their conviction that death had resulted from no improper or injudicious treatment, but was consequent upon intestinal and peritoneal mischief set up by fever.

The Coroner hereupon addressed the jury, and expressed his belief that any doubts previously entertained relative to the unsoundness or unsafety of the medical treatment which had been adopted towards deceased must, after the investigation that had been made, be entirely removed from the mind, and submitted to them the propriety of returning a verdict in accordance with this view: a recommendation which the jury instantly acted upon; in what precise words, however, we are unable to state; and thus terminated an inquiry of much professional interest in more lights than one.

HALIFAX UNION.

A Summary of Visits and Medicines supplied to Poor-law Patients for a period of Thirty-one Days, commencing May 20, and terminating June 19, 1847.

HALIFAX DISTRICT.

DATE.	Visits.	Mixtures.	Pills.	Powders.	Lotions.	Liniments.	Ointments.	Plasters.	HALIFAX DISTRICT. Area 990 Acres. Population 19,881
1847, May 20	13	11	49	5	1	0	0	1	OBSERVATIONS. Remuneration £80 per annum; that is 4s. 4d. per day; or for the attendance and medicines here enumerated, being for a period of 31 days, £6 15s. 7d. This scale of remuneration is equivalent to 3d. for each visit, the medical officer having also to supply, for this sum, the requisite medicines. Of these, it will be seen, form an item of considerable magnitude, and the house of the medical officer who distributes medicines in this way is no longer a private establishment, but a public dispensary. There is enough here to speak for itself; and I am not ashamed to submit this paper to the patient and candid consideration of the Board of Guardians of the Halifax Union. Figures are incontestable; and I vouch for the accuracy of this document in every particular. (Signed) FRED. SMITH GARLUCK, Medical Officer for the Township of Halifax.

GOSSIP OF THE WEEK.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma of this college, were admitted members on Friday evening, the 16th inst., viz.: Messrs. J. T. Jones, Farthingstone, near Weedon, Northamptonshire; John G. Winstone, Redgrave-street, Fleet-street; James Leslie, Arran, Ireland; John Octavius Dukes, Shrewsbury; Frederick Greenwood, Huddersfield; Thomas Balle Forster, Plymouth; Fred. Farmer, Dublin; William George Gill, White Lion-street, Pentonville; James Lancashire, St. Mary's, Lancashire; William Thomas

Domville, Royal Navy—this gentleman passed as naval assistant in July, 1842; William Foot Vidal, Aveley, Essex; and Herbert Shelley, Epsom.

THE MEDICAL PROFESSION OF IRELAND.—THE BOARD OF HEALTH.—At a meeting of the physicians and surgeons of Galway it was resolved "that any person holding the diploma or degree of any recognised college, who will so far degrade his own character and forget that of his college, as to accept of the paltry sum of five shillings per day offered by the Board of Health to a medical man for his services in a temporary fever hospital, forfeits his right to be considered a medical gentleman, and that, consequently, we

decline to meet him in consultation. That we would prefer giving gratuitous attendance in these hospitals, rather than stoop to receive the remuneration offered by the Board of Health."

LUNATIC ASYLUMS OF THE UNITED STATES.—On the 1st of January, 1846, the number of patients was 3377. Recently several new physicians have been placed at the head of some of these establishments: these are Dr. Andrew McFarland, New Hampshire; Dr. Chandler, for the state of Massachusetts; Dr. John Jorden, Maryland; Dr. J. W. Parker, South Carolina; Dr. T. F. Green, Georgia; Dr. John S. McNary, Tennessee. Two new asylums have been erected: one at Indianapolis, in Indiana, to which Dr. John Evans has been nominated physician; the other at Trenton, in New Jersey.

EGYPTIAN SURGERY.—TETANUS CURED BY ETHER.—A young man, named Abdul Gebian, was admitted into the hospital for traumatic tetanus, characterized in the clearest manner. M. Franc administered the ether in large doses, and he succeeded by this sedative remedy in curing the disease. The opisthotonos and tetanic spasm gradually yielded, and in twenty-eight days the malady was cured.

APOTHECARIES' HALL.—Gentlemen admitted members July 15: Henry Alfred Warburton, James Braid, Chappell May Empson, James Lancashire, Oliver Lamberton, and Hugh Robert Rump.

OBITUARY.—At Liverpool, Nova Scotia, on June 24, in his 27th year, Ebenezer Annan, Esq., surgeon, only son of Robert Annan, Esq., surgeon, Kinross. He was an old pupil and much attached friend of Dr. Knox.—On the 10th inst., at Primrose-hill, Coventry, Henry Ronalds, M.D., aged 59.—On the 10th inst., at 53, Pall-mall, George Buckley Bolton, Esq.—At Broadwater, Sussex, on the 10th ult., much lamented, Charles Maybery, Esq., surgeon, R.N., in the 57th year of his age.—On the 19th inst., in Craven-street, Dr. Tobin, R.N., surgeon of Her Majesty's Dockyard, Devonport.—On Tuesday, the 18th, William Masters, Esq., curator of King's College Museum of Anatomy, of an attack of pericarditis. He was deservedly esteemed by those who knew him, both for his general character and scientific attainments.

MORTALITY TABLE.

For the Week ending Saturday, July 17, 1847.

Causes of Death.	Total.	Average of 5 Summers.
ALL CAUSES	944	940
SPECIFIED CAUSES	940	935
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	229	226
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable Seat	108	103
Diseases of the Brain, Spinal Marrow, Nerves, and Senses	140	157
Diseases of the Lungs, and of the other Organs of Respiration	245	226
Diseases of the Heart and Blood-vessels	82	25
Diseases of the Stomach, Liver, and other organs of Digestion	101	94
Diseases of the Kidneys, &c. Childbirth, Diseases of the Uterus, &c.	8	8
Rheumatism, Diseases of the Bones, Joints, &c.	9	10
Diseases of the Skin, Cellular Tissue, &c.	8	7
Old Age	1	2
Violence, Privation, Cold, and Intemperance	40	50
	19	26

THE MEDICAL TIMES.

No. 409.

SUMMARY.

JULY 31.

ORIGINAL LECTURES—

Suggestions for a more simple Arrangement of the Materia Medica, by G. L. ROUPELL, Esq. 443

Course of Lectures on Clinical Medicine, delivered at Queen's College, Birmingham, by S. WRIGHT, M.D. 444

On the Physical Phenomena of Living Bodies, by Professor MATTEUCCI, of Pisa 416

DUMAS on Organic Chemistry—On the Milk.... 448

ORIGINAL CONTRIBUTIONS—

On the Physiological and Pathological Causes of Sudden Death in Connection with the Vascular or Circulatory System, by M. W. HILLES, Esq. 450

Fracture of the Cervix Femoris at an Early Age, by C. H. HALLETT, Esq. (with Engravings) 451

A Singular Case of Partial Erection of the Penis, by Dr. C. CLAY 453

Phlegmonous Erysipelas from Slight Wound in the Hand, by C. EDWARDS, Esq. 453

PROGRESS OF MEDICAL SCIENCE—

Academy of Sciences; Meeting of July 19 454

Sparkling Quinosis 454

Effects of Quinine on the Bladder 454

Academy of Medicine; Meeting of July 20 454

Treatment of Hiccough by Pressure on the Epigastric Region 454

Signs indicating the Presence of Worms..... 454

MISCELLANEA

ROYAL MEDICAL AND CHIRURGICAL REVIEW—

Report on the Climate and Principal Diseases of the African Station, by A. BRYCE, Esq. 455

Surgeon R.N. 455

CORRESPONDENTS

LEADERS—

The Government Answer to the Irish Language Bill 455

Protest 455

Poor-law Guardians and Medical Officers 455

Medical Apprenticeship 455

GOSSIP OF THE WEEK.....

MORTALITY TABLE

SUGGESTIONS

FOR A MORE SIMPLE ARRANGEMENT OF THE

MATERIA MEDICA,

BASED ON ITS PHARMACEUTICAL AND THERAPEUTICAL RELATIONS.

By GEORGE LEITH ROUPELL, M.D.

Cantab., F.R.S., Fellow of the Royal College of Physicians, Physician to St. Bartholomew's Hospital, Lecturer on Materia Medica at the College of St. Bartholomew's.

(Continued from p. 386.)
LECTURE IV.

Next to morphia on my list is placed—2. Atropia, the active principle of the belladonna.

Atropia, now in extensive and daily use, appears in the form of small white crystalline prisms, soluble in all proportions in alcohol, in fifteen parts of ether, and to a certain extent in water. It volatilizes in close vessels at a temperature of 212°. It is inodorous, and is described as having a bitter, disagreeable taste.

It has an alkaline reaction, its symbol is *At*, and its formula *C¹⁷ H¹⁹ O³ N*. The root, the berries, and the leaves of the belladonna all contain it.

Strong alkalis decompose atropia, but it combines with acids. It exists naturally in the form of a malate, but the sulphate is the salt commonly made artificially. It is to be remembered that its salts are to a certain extent volatile at the ordinary temperature of the atmosphere, and to a much greater degree by heat.

Sulphate of atropia, made by adding sulphuric acid to pure atropia, usually appears in the form of minute white grains, but, if alcohol containing it in solution be allowed to evaporate slowly, it exhibits masses of crystals radiating from a centre.

The sulphate of atropia is solely employed as an external application, and its chief use is for the purpose of dilating the pupil of the eye. This property is enjoyed by several of the natural order Solanaceæ, but none possesses it in a more remarkable degree than atropia, of a grain of which suffices to produce this singular result.

The objects for which the dilatation of the pupil is resorted to are—

1. In order to obtain a better view of the parts of the eye behind the iris.

2. To enable persons labouring under cataract in certain stages to enjoy vision.

3. To prevent adhesions of the iris in cases of inflammation of that part.

4. For the better performance of certain operations upon the eye.

When the pupil has been well dilated by atropia the interior of the eye may be rendered visible, even to the bottom of the orbit. In central cataract, both lenticular and capsular, dilating the pupil enables the patient to use a sound portion of the capsule or lens for vision.

By dilating the pupil in iritis the formation

of adhesions will be prevented, and when of recent date they may be broken down. Atropia should be used in conjunction with the active measures for subduing inflammation, and for promoting the absorption of lymph.

It is essential that the pupil of the eye should be dilated previously to the operation by solution or keratonyxis, and that by depression or couching. Some operators, however, prefer, others object to, its use in the extraction of the lens.

The internal use of the pure alkaloid atropia is not yet in the hands of the regular practitioner; but great benefit would be conferred on the community at large were the dose well ascertained in which this and other powerful bases could with safety be exhibited, and should the symptoms resulting from its employment in appreciable quantities be accurately observed and recorded. Atropia, as prepared by Brandes, when given to animals, occasioned an action as rapid, and produced death as instantaneously, as hydrocyanic acid.

At present we are required to employ internally the official preparations of belladonna, which, as ordinarily made, are not unfrequently inert, for reasons obvious enough when we perceive that heat is employed in the processes directed, and when we recollect the volatility of the salts of atropia.

The official preparations are the dried leaves, the extract, and the plaster.

Belladonna acts upon the nervous and muscular systems rather than upon the vascular and secretory ones. Still we find some results from its exhibition which show an influence over the vessels and the secretions from certain portions of the mucous tissues.

The action of belladonna upon the nervous system, when taken internally in small doses, is that of allaying pain and checking spasm; its action upon the vascular system is that of occasioning an efflorescence on the skin. In larger doses it produces active, furious, or mirthful delirium, ending in coma, alternating again with wildness, accompanied by great and permanent dilatation of the pupil, by impairment of sight, and other disturbance of vision.

Dryness of the throat is much insisted upon as characteristic of the action of belladonna; this, however, is not invariably present, though

The indications for its employment, upon observation of its effects, are—

1. The prevalence of a certain infective disorder.

2. Certain painful affections.

3. Some forms of spasmodic disease, and co-

4. Certain profluvia or discharges. Belladonna has been vaunted as a specific against scarlatina; and the question, unless easily cannot yet be considered as quite natural, therefore deserves a trial in those at the best infection when scarlatina is passed on local fatal.

The painful affections benefited by under consideration are those chiefly of the character, that is, unaccompanied by two months such as are less urgent in degenerated. The chronic in duration than those it was with the exhibition of morphia. The local effects of belladonna, it may here be observed, are often under such circumstances singularly efficacious.

Nervous and other palpitations, spasmodic cough, whether with or without, and otherwise, are some of the spasms, consequently, relievable by belladonna; and the local application in spasmodic affections of the sphincters of the urethra and bladder, as well as in rigidity of the os uteri, more feasible of parturition, is undoubted.

The ancient employment of inhalations of the leaves of belladonna has long been preserved on the Continent. The leaves, when placed on a heated coal, gives off a soft, styptic, be highly sedative in coughs, and little; appetite hemorrhage from the lungs.

The subject of belladonna cannot without noticing the high susceptibility whatever of persons to its influence, or without great nervous the fact that its external application could only call sufficient in some cases to produce of known-constitutional symptoms.

Belladonna differs from opium in being one of lessening the disposition to sleep, intrinsic morbid the secretions from the bowels, arising, we could upon the eye, in which, with regard to its for treatment, it is exactly antagonistic.

3. Hyoscyamia or hyoscyamus of wine daily, from the hyoscyamus niger. It is crystallizing in long prisms, ison carb., Sol. disagreeable qualities both of its large, due ter

ment: the faculty she recovered was as perfect as it had ever been, but the interval between its loss and its restoration was a perfect blank—she might not have lived during that time, so ignorant was she of the events of it.

About nine months ago, I attended, with Mr. Carter, a little boy, six years of age. A few weeks previously to our first seeing him he was a fine healthy little fellow, full of energy, and in the enjoyment of more than an average share of intelligence. In the absence of his mother, one day, a brute in human shape thrust the child into a dark cellar, in punishment for some trivial offence. He was incarcerated for two hours, and his poor mother, on her return, liberated, not the child she had lost, but an idiot. The silly gabble of fatuity was all the welcome she had from the boy that, two hours before, had been her rational companion! In a few days speech entirely left him, and there was nothing but the vacant stare and grimace of idiocy. Within a week he lost the power of locomotion; and, when we first visited him, he was paralyzed as well as foolish.

Gentle aperients, and diffusible stimulants, with good living, and, subsequently, strychnine and change of air, considerably restored his physical powers, and in some measure improved the condition of his mind. The latter, however, is still weak and wandering, and I fear will ever remain so.

Had this boy died when at the worst, would anything have been discovered in the brain or spinal cord to account for the loss of intelligence and of the power of locomotion? It is not improbable that some organic alteration or other might have been recognised, but it is, perhaps, more probable that there would have been no appreciable change of structure whatever. I say appreciable, because I do not wish you to understand that I am speaking in absolute terms. The expression "discovery," or "non-discovery," bears reference to our physical aptitude of making it in the cases I have referred to. The absence of change in any part, according to the evidence of our senses, must always be taken with a qualification derived from the fact that our senses are not infallible. We know nothing of function, except in connection with structure—function is not an entity, or an abstraction, but a manifestation of matter. We cannot, therefore, imagine any change to occur in the effect, except as a consequence of some change in the cause. Hence we infer that, in the instances of paralysis apparently unconnected with organic lesion, this latter is not absent, but is too delicate for our senses to appreciate it. Late researches in organic chemistry, and the microscope, have revealed to us many minute shades of difference in the composition and structure of organs that were previously not known to exist; and the anticipation is rational enough, that future investigation will introduce us to yet more subtle secrets of our organism, and of the actions that issue from it. But, with all that we have done, and with all that we hope to do, there are truths that pass our comprehension, and *minutiae* into which we shall never pry. There are certain errors and eccentricities of function, which we can no more hope, in all our pride of scrutiny, to scan, than we can expect to question any of those final causes which are wisely excluded from the limits of our knowledge.

In the humility, then, which an assurance of our imperfect understanding ought ever to impose, we must be satisfied with approximative truths when absolute ones are denied us; content with partial evidence when plenary is unattainable. This is an obedience to unavoidable difficulties which it is often the wisdom of a medical practitioner to pay. Your first object, as I have often told you, in treating a case, is to search for its cause; but, failing to find this, do not, therefore, desert your charge, but be satisfied to act upon a rational surmise, and upon the testimony of symptoms. The metaphysical practitioner, the finality-man, who affects to see deeper into the depths of things than can his more

honest and straightforward neighbour, is often very much in the way at the bedside. Many a philosophical-headed fellow has let a patient slip through his fingers by some medicable means, whilst disputing with himself about some elemental fact in the case that would just as well have been left alone. Let me caution you against the grand impertinence of being thought wise over much.

But I must leave this digression for the cases that have called it forth.

About the latter end of October, last year, a middle-aged man, named Price, came to the hospital as an out-patient, complaining of paralysis of the left leg, from the knee downwards. He was a button-maker by trade, had led a steady life, and always enjoyed good health until the occurrence of his present ailment, for which he could in no wise account. About three weeks before we saw him he felt some little difficulty in walking, from a sensation of weight in the left foot. Shortly its sensibility began to diminish, as also did its temperature: the numbness and coldness rose to his knee, but did not go beyond it. The occurrence of these things was quite unconnected with any other appreciable disorder or suffering. He had no pain in any part of his head, or in any part of his body. He ate and drank, and slept and worked, and was in as good spirits as usual; and his excretory functions were regular and natural. On the occasion of his first visit to the hospital, it was with the greatest difficulty that he contrived to walk, even with the assistance of a friend's arm and a stick. The manner in which he threw the leg forward showed clearly how imperfectly he could command it. This leg was very sensibly colder than the opposite, and was very little susceptible of external impressions. It was neither swollen nor shrunken, nor in any part discoloured. The man had no pain in his head, or elsewhere; no confusion of mind; no irregularity or imperfection of vision, or ringing in his ears; no tenderness of the spine on pressure; his tongue was clean; appetite and digestion good; pulse substantial and steady; sounds of the heart natural; and all the secretions appeared to be healthy. Apart from the local ailment, it was impossible to say that the man laboured under the least manifest disorder.

Taking into consideration all the items I have specified, there was no ground for the inference that there was any organic mischief in the brain or spinal cord; and I told you, the conclusion seemed warrantable that the affection was purely local, and perhaps due to some loss of power, merely, in the nerves distributed below the knee. There was no evidence of pressure on any nervous trunk, from tumour or other cause, and the circulation was not radically at fault, for it had become weak secondarily to the impairment of the nervous function. I regarded the case simply as one of diminished power, from no assignable cause, and as requiring nothing more than local stimulation. The following liniment was ordered:

R. Liniment. saponis comp., ʒijss.; tinctura lytta, ʒss. Misc. fiat linimentum applicandum parti affecta nocte maneque.

This was assiduously applied for the space of a week, but without producing the least sensible effect. The linimentum camphorae compositum was then substituted for that of soap, and the proportion of tinct. lytta increased to six drachms.

In two days after having begun to use this, a tingling sensation was felt in the toes, gradually spreading thence over the foot, and at length over the leg, as high as the knee—taking just the same course, and keeping within the same limits, as the original numbness. This, I told you, was a favourable symptom—it is a frequent precursor of recovery in cases of uncomplicated paralysis. The liniment was ordered to be continued, and, before a week had elapsed, its application occasioned considerable pain. The returning sensibility was now very apparent. The quantity of tinct. lytta was reduced to one half, the liniment to be applied only once a day: this

degree, sensibility and power were restored, and on the patient's last visit, a month of his first, he had no complaint left. In every appreciable respect, the leg was as well as suffered was equal to its fellow.

During the following seven months, the man continued in the enjoyment of his usual good health, and his leg was as well as it had ever been. At the beginning of June, however, he came to the hospital again, complaining of diminished sensibility and power in the same leg. The affection was much milder than the previous one, and this time was obviously connected with gastro-intestinal derangement. His tongue was furred; appetite bad; digestion tardy, painful, and always accompanied with much flatulence; urine scanty and high-coloured; bowels costive. This state of derangement had existed for a fortnight, and about a week after its occurrence his leg began to fall, and had continued to do so up to the time of his second application at the hospital.

After carefully examining the man, there was nothing, as I told you, to lead to the suspicion that his gastric disorder arose from serious causes, or that ordinary treatment would not relieve it. The recurrence of the partial paralysis was no matter of surprise. I looked upon his second visit as one of the many proofs we meet with of an injured or an impaired part suffering proportionately to a deterioration of the general health, or a defect in the function of nutrition. The object in this case, as I said, was to correct the state of the stomach and bowels, and it was not improbable as these improved that the leg would improve also. With prescribed diet, the following medicines were given:—

R. Inf. cascariillæ, ʒviij.; ammon. carb., ʒss.; sp. eth. nit., ʒij. M. ft. mist. cujus cap. coth. amplia duo ter die.

Cap. omni nocte, pil. thei comp., gr. x.

In a few days the gastro-intestinal condition began to improve under this treatment, and coincidentally with the amendment the leg began to recover its power and sensibility. The relationship of the reparatory processes continued, until the digestive function had become quite natural, at which time the leg was as well as at the best it had been. In this instance we used no local application whatever. Up to this time, the man has remained in excellent health.

You remember a patient named Sutcliffe, who occupied the top front ward about two months ago. His left arm and leg were paralyzed. The paralysis was not complete, but it was with the greatest difficulty the man could walk across the room—he could not raise his hand higher than his shoulder, nor close it with any degree of force. He was a shoemaker by trade, had enjoyed pretty good health up to six months previously, when his business declined, and he suffered many domestic privations, consequent upon which came his paralysis. This had existed about eleven weeks, and had gradually got worse. The affected limbs were colder than natural, and the pulsation in them more feeble than on the opposite side. The man had a very pale, emaciated look, and his muscles were generally very flabby; tongue trembling when protruded, indented at the edges, and covered with a white fur; pulse 96, small and soft; systolic sound of the heart scarcely audible; appetite bad; troublesome gastric flatulence; urine copious and limpid.

In this case there was no evidence whatever of appreciable organic lesion in the great nervous structures. I told you that we could only call it lesion of innervation, in the absence of knowing the precise condition from which this might arise. The leading manifestation was one of debility, and, not knowing the intrinsic morbid state from which this might spring, we could only take the symptomatic condition for our pathological guide and authority for treatment. He was ordered full diet, a glass of wine daily, and the following:—

R. Infusi cuscutæ, ʒviij.; ammon. carb., ʒij. M. ft. mist. cujus cap. coth. amplia duo ter die.

R. Pil. rhei comp., assafœtide, aa. 3ss. M. divide in pil. xij. quarum cap. ij. omni nocte.

Not many days elapsed, after commencing this treatment, before the appetite and digestion began to improve; this amendment was shortly followed by augmented strength and warmth in the affected limbs. At the end of a fortnight the man could walk with some comfort, and occasionally strolled into the garden: he could raise his hand above his head, and give a tolerable grasp. During the following week he continued to improve, and the last time we saw him I remarked, that in a few days he might become an out-patient. Before our next visit, however, he took some offence at a fellow-patient and left the hospital without any ceremony, or expression of gratitude. This manifestation of sauciness, like the peevishness of children, was, perhaps, the best testimony we could have of his improved health and vigour.

There is a little girl at this time under my care in the top ward: she came in, three weeks ago, the subject of general weakness, and of very diminished sensibility and motility of the right leg. She has lately grown fast, and her mother considers this weakness to be the result of the rapid growth. From the first I believed the mother to be right, for there was none other assignable cause for the manifest debility. The girl was put upon full diet, and ordered a bitter infusion, with muriate of iron, three times a day. When we last saw her she walked with little difficulty; her appetite has vastly improved, and her complexion is getting ruddy. I have no doubt that in a few days she will be fit for dismissal.

About eighteen months ago, I had a dispensary patient under my care, the subject of dyspepsia. In the process of her recovery she lost the use of her left arm. There was nothing whatever to account for it, and I therefore treated the affection as purely local. She was ordered fomentations of hot mustard and water thrice daily; these soon produced signs of amendment, but it was not effectual until after the application of a stimulating liniment, under which the restoration became complete.

I had once a case of paralysis of one leg, which supervened upon suppressed menstruation. The uterine function was restored by purgatives and chalybeate tonics, but the paralysis remained the same. It was cured by a succession of blisters to the hip.

You often meet with imperfect paralysis from a limb having been placed during sleep in some particular position. In most cases of this kind, the affection is only temporary, and either passes off spontaneously, or is readily relieved by some stimulating application. Sometimes, however, these cases are very troublesome and almost set treatment at defiance. I have seen more than one, in which recovery, after various means had been used, was incomplete. This generally happens to old subjects. I have a case at this time under my care at the dispensary, in the person of a middle-aged man, who awoke one morning with his arm twisted under his head. He had never had a symptom of paralysis in his life, and had gone to bed in his usual good health, but on getting up he found his arm useless. He tried friction, and various stimulants himself, but to no purpose: these were repeated more energetically at the dispensary, for upwards of a week, but without effect. Galvanism has since been employed, and with good results. Mr. Carter galvanizes the limb, well, every other day, and the progress is so satisfactory that I have no doubt only a few more applications will be necessary.

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART VII.

ARTERIALIZATION—NUTRITION—ANIMAL HEAT. By arterIALIZATION we understand the modification in the constitution of the blood which takes place in the act of respiration, and is accom-

panied and indicated by change of colour, evolution of carbonic acid, and absorption of oxygen from the inhaled air, as has been fully stated already in the preceding part. We will now endeavour to investigate this modification in its details.

Which of the organic elements of the blood suffers this modification?—and in what does it chemically consist?

It must be confessed that these are questions which, although studied by many distinguished physiologists and chemists, have not yet met with anything like a full and satisfactory solution. Amidst the immense number of conflicting facts and deductions that have been furnished on the subject by its investigators, we will here select those which appear least imperfect and contradictory.

Microscopic observers of the present day define the blood as an aqueous liquid holding in solution various salts, albumen, fibrine, fatty matter, and in suspension a great number of red globules of definite form, and greater or less size, according to the divers respective animals.

These globules may be separated from the blood by filtration through bibulous paper. The globules will remain on the filter; the filtrate, which is of a yellowish colour, coagulates soon after filtration; the clot consists of fibrine. In unfiltered blood, drawn from the living body, the fibrine coagulates, enveloping in the clot the suspended globular matter. The coagulation of blood is accelerated, promoted, and otherwise influenced by purely physical circumstances, such as its temperature, the density of the serum, the respective proportion between the globules and the fibrine, &c.

The coagulum of blood drawn from the living body assumes a vermilion tint when treated with oxygen. When exposed to the air, and subsequently cut, it is found externally of a florid red, and in the internal part of a blackish colour. The cut surfaces, exposed to the air, acquire speedily a red colour. That it is the globules of the blood which undergo this change of colour is unquestionable. Baudrimont and Martin St. Ange have recently shown that absorption of oxygen and exhalation of carbonic acid take place through the calcareous envelope of the egg at the period of incubation, and have proved that, if these phenomena are prevented, the undeveloped embryo does not, as usually, present small red globules. Whether the globules of the blood acquire their florid tint simply by the absorption of the atmospheric oxygen or loss of carbonic acid during respiration, or whether, on the contrary, the arterial blood is changed to venous by the accession of carbonic acid, or separation of oxygen, is not yet clearly established. Magnus has proved that the separation of the largest possible amount of carbonic acid from venous blood, although brightening the dark hue of the latter, fails to produce the florid arterial tint. This would lead us to assume a joint influence of the two causes in the change of colour which the blood suffers in the act of respiration. We may add here, that a coagulum that has been carefully freed from every trace of serum adhering to it does not quite acquire the usual fine vermilion tint upon exposure to oxygen. If a saturated solution of sea salt be dropped upon a coagulum, perfectly freed from serum, and guarded against access of air, the spots touched by the solution will exhibit a vermilion tint, whilst the rest of the coagulum will continue to present a dark venous hue. Thus it would appear that the salts of the serum likewise exercise a certain influence in the modification which the colour of the blood undergoes in presence of oxygen. We know that serum absorbs a quantity of carbonic acid, much more considerable than the water of this fluid can possibly dissolve. We might, therefore, assume that the influence which the presence of the serum exercises in the change of colour of the blood consists in the absorption of the portion of carbonic acid which the oxygen subsequently removes from it.

In what does the change of colour of the

globules of the blood *chemically* consist? Upon this point science is still altogether in the dark. The large proportion of iron (five to six per cent.) constantly present in the globules of the blood, and which exists to the same extent in no other animal substance, has led to the supposition that this metal—which is found in the globules sometimes as protoxide, and at others as carbonate—performs a part in the change of colour of the blood. We know that oxygen expels carbonic acid from carbonate of iron, and that, on the other hand, carbonic acid may replace the oxygen of the peroxide of iron, according to the relative proportions of oxygen and carbonic acid present.

Mulder and Liebig seem to adopt this notion. Clinical experience seems to prove that the administration of iron in certain diseases revives in some sort the colour of the blood. Scherer,

however, has lately asserted that he obtained the colouring matter of the blood entirely free from the slightest admixture of iron. Should this be confirmed—and should it be proved, moreover, that the colouring matter thus deprived of iron undergoes, in contact with oxygen and carbonic acid, the same modifications as the globules of the blood—we shall, of course, be forced to renounce the notion, that iron performs a part in the change of colour of the blood.

The arterial blood, propelled by the incessant contraction of the heart and the successive dilatations and contractions of the walls of the arteries, is carried to the last capillary ramifications, in which it traverses all the tissues; it then loses its vermilion tint, returns to the heart through the venous vessels, and passes again through the lungs. It is in the passage of the arterial blood through the capillaries that the phenomenon of nutrition is effected. Physiology assumes that all parts of the animal tissues are incessantly being renovated and transformed, and that this renovation and transformation vary in intensity according and in proportion to the greater or less degree of activity possessed by the respective capillary systems of the divers tissues. The correctness of this assumption, although by no means proved *experimentally*—for the coloration of the bones of animals fed upon coloring matter, and its cessation upon the discontinuance of that diet, cannot well be looked upon as sufficient proof—is yet sufficiently demonstrated by physiological facts. The red globules—not forming part of any tissue, and yet essential as they are to nutrition—may be looked upon with a certain appearance of probability as the catalytic body which solicits or induces the transformation of the tissues and their incessant renovation; the fact that the absorption of oxygen is necessary to impart this catalytic property to the red globules speaks in support of this view. Let it be remarked, moreover, that in the same way as diastase converts starch into dextrine, &c., so the red globules of the blood may convert albumen into fibrine; and this conversion certainly occurs in the embryo.

In the act of nutrition a portion of the arterial blood disappears, and is replaced by an excess of carbonic acid in the venous blood. In the capillary vessels the oxygen combines with the carbon; and, if we find subsequently that the volume of carbonic acid exhaled is smaller than that of the oxygen that has disappeared in respiration, we are led to the conclusion that, besides the carbon, the hydrogen, which forms part of the organic elements of the blood and tissues, combines with the oxygen to form water.

The acetates, tartrates, and oxalates, which enter the circulatory current in a state of solution, are eliminated in the form of carbonates through the urinary organs. Benzoic acid, introduced into the circulation, is eliminated through the same organs in the form of hippuric acid. The author and Professor Piria introduced a solution of salicine into the blood of a living animal: after a certain time they detected in the urine a body which derives from salicine, and possesses the property of forming violet precipitates with salts of iron.

Desessals found that, upon boiling hippuric

acid in a solution of hydrochloric acid, benzoic acid precipitates, and the solution contains now the hydrochloric acid in combination with a nitrogenized saccharine substance (Braconnot's sugar of gelatine). We know that this substance is produced by treating neutral nitrogenous substances (gelatine, proteine) with acids; we know, likewise, that the secretion of hippuric acid replaces in the herbivora the secretion of urea in the carnivora; we may, accordingly, assume that the sugar of gelatine is one of the first products of the transformation of the neutral nitrogenous matters which form the materials of the tissues; which would account for the elimination of hippuric acid subsequent upon the introduction of benzoic acid into the circulation.

All these facts prove beyond question that the principal chemical action observed in the circulation of the blood and in the process of nutrition consists in combustion, viz., in the combination of oxygen with carbon and hydrogen. We must, however, repeat here, that our knowledge of these phenomena is very limited and unsatisfactory indeed. What difference exists between the chemical composition of all the elements of the arterial blood and that of all the elements of the venous blood? Of what nature is this difference in the blood before and after its passage through the kidneys, the liver, and the divers tissues? These are some of the numerous questions that ought to be solved by the most precise experiments and researches, before we can venture to proceed to investigate the phenomena of nutrition and secretion.

We saw, in a preceding part, that the food passes into the blood after having undergone divers modifications in the process of digestion. Of the various aliments, many are identical with the organic elements of the animal tissues: this is the case, for instance, with the neutral nitrogenous matters, and also with the fatty matters which are found in the organism, either unaltered, or, as in the adipose tissue, but very slightly modified. It is not natural, and would even appear strange to admit, that urea, carbonic acid, and water—the ultimate products of the transformations suffered in the process of nutrition—proceed from the organic elements of the blood introduced into that fluid by alimentation. These products are to be considered rather as resulting from the transformations of the tissues, where they are replaced by fresh supplies of organic elements furnished by the food; and, in fact, the production of urea continues in animals fed for a long time upon sugar, starch, or gum the same as before that alimentation was resorted to. The same continued production of urea has been observed in the case of animals altogether deprived of food, and which subsequently died from inanition. A serpent that has been deprived of food for some time, and is subsequently supplied with a goat, a rabbit, or a fowl, voids the excrements, hair, and bones of the devoured animal, exhales carbonic acid and water, and eliminates through the urinary organs ureate of ammonia alone: it recovers, subsequently, its usual weight, and there remains not the slightest trace of the devoured animal. —(Liebig's "Organic Chemistry applied to Animal Physiology.")

Let us analyze this simple case of nutrition. Urate of ammonia contains one equivalent of nitrogen to two equivalents of carbon; the muscles and blood of the devoured animal contained eight equivalents of carbon to one of nitrogen; and, if we add to this the carbon of the fat and brains of the devoured animal, we find that the serpent has taken above eight equivalents of carbon to one of nitrogen. In the excrements are found only two equivalents of carbon, the remaining six equivalents must have been eliminated in the form of carbonic acid.

The same is the case with the lion and all the other carnivora: urea alone is found in their urine. As these animals feed upon flesh—a substance in which the proportion of carbon to nitrogen is like eight to one;—it follows that the excess of the carbon introduced into their organ-

ism over that eliminated in the urine is consumed in the act of respiration, being converted into carbonic acid. The respiration of the lion is certainly more active than that of the serpent.

The fifteen or twenty grammes of nitrogen eliminated daily in the urine of man, and the excess of nitrogen exhaled, proceed from the neutral nitrogenous matters in the food, or, to speak more correctly, from the transformed tissues replaced by the alimentary substances.

Boussingault has proved experimentally that the urine of the horse does not contain the whole of the nitrogen contained in the food of the animal; and he argues thence that the excess of nitrogen exhaled proceeds likewise from the food.

In the actual state of chemistry and physiology, it is impossible to say, with any degree of precision, through what series of modifications and intermediate products the muscles, cartilages, &c., have to pass, preparatory to their final conversion into urea by the action of the oxygen of the globules of the blood. If we add to the formula of proteine (which is equally that of albumen, fibrine, caseine, &c.) as much oxygen as is required to convert this substance into urea, and the excess of hydrogen and carbon into water and carbonic acid, we obtain quantities of the latter substances much smaller than those produced in the act of respiration. The following figures, deduced from Boussingault's experiments, will clearly show that the proportion of the carbon contained in the nitrogenous elements (which are ultimately converted into urea) is greatly below that emitted in the form of carbonic acid, in the act of respiration. A perfectly healthy horse consumed per diem 1½ kilogramme (above three pounds English) of hay, and 2½ kilogrammes (above 4½ pounds English) of oats. Analytical examinations show that the proportion of nitrogen contained in hay is 1.5, and that contained in oats 2.2, per cent. Admitting that the whole of the nitrogen contained in the food passes into the blood, in the form of albumen and fibrine, this would make 110 grammes of nitrogen introduced into the blood, and destined to replace the nitrogen which separates in the products of the transformed tissues. The quantity of carbon introduced, in conjunction with the nitrogen, amounts to 110 grammes, of which only 238 are free to combine with oxygen to carbonic acid in the act of inspiration, since the horse eliminates in the urine 93 grammes in the form of urea, and 109 grammes in the form of hippuric acid. But Boussingault's experiments show that a horse exhales in respiration, in twenty-four hours, 2151 grammes of carbon, in the form of carbonic acid, which clearly proves that the carbon of the nitrogenous principles of the food forms only a small portion of that which is contained in the carbonic acid exhaled in respiration. Hence arises the necessity for the animal to supply by other articles of food—such as starch, gum, sugar, fatty substances—this deficiency of carbon in the nitrogenous matters. The food of young animals contains a larger proportion of those matters that furnish carbon and hydrogen, and are eliminated in the act of respiration; by this means the nitrogenous substances intended for the growth of the tissues are husbanded.

Dr. Capezzuoli determined successively the weight of the fatty matters and neutral nitrogenous substances contained in hens' eggs during the period of incubation, and ultimately in the newborn chicken; he found that towards the seventeenth day of incubation, and accordingly a short time before the birth of the chicken, there occurs a sensible diminution in the quantities of fatty and neutral nitrogenous matters, and that this diminution goes on slowly increasing in the young animal.

With regard to the fatty matters, it would appear that they likewise are made to subserve the exclusive purposes of respiration only in cases where the amount of starch, gum, or sugar introduced into the organism is insufficient. Thus, animals left for a long time without food—as those, for instance, that sleep during the winter months

—lose their fat during these periods of abstinence. The fatty matters seem primitively intended for the formation of the cerebral and nervous substance, and to fill up the meshes of the cellular tissue, which is not without importance for the functions of life, and forms, as it were, a kind of reserve depot for the materials required in the process of respiration.

With regard to the bile, no physiologist of the present day fancies that this substance is simply an excrement. Berzelius found in 1000 parts of human excrements only nine parts of a matter similar to bile; accordingly, an individual who secretes from 500 to 700 grammes of bile per diem, rejects in his excrements only the 1-50th or 1-75th part of the bile secreted. On the other hand, it is difficult to believe that a matter so slightly nitrogenized as bile is, can be useful for the purposes of nutrition. We saw, in a preceding part, that bile has no, or only a very trifling, share in the process of digestion. Liebig asserts that the bile flowing into the duodenum forms a soluble compound with soda—that it is absorbed and converted into carbonate of soda—yielding thus a portion of its carbon to the oxygen. This view is not supported by experimental proofs; and it is, moreover, only in some pathological cases, and under the influence of certain atmospheric constitutions, that traces of biliary matter have been discovered in the blood.

It has been stated in a preceding part, that an adult absorbs 1015 grammes of oxygen per diem; it results from the observations of Dumas, Andral, and Gavarret, and the more recent ones of Scharling, that an adult exhales in twenty-four hours, 224 grammes of carbon in the form of carbonic acid; that males exhale more carbon than females, and children more than adults; and that more carbon is exhaled during day than at night. A horse eliminated in the form of carbonic acid 2155 grammes of carbon, for which purpose it consumes 6501 grammes of oxygen. A milch cow exhales 2212 grammes of carbon in the form of carbonic acid, consuming 5833 grammes of oxygen. Thus we see that there exists a relation between the quantity of food consumed, and the amount of oxygen absorbed and carbonic acid exhaled. The activity of the respiratory movements, the density of the inhaled air, and the quantity of carbon introduced with the food, must be in proportion to one another, in order to preserve the materials of the animal economy. Letellier has recently shown, by experiments made with birds and guinea-pigs, that the amount of oxygen consumed in respiration is less in proportion as the temperature of the air is higher. At 32° Fahrenheit, his observer found the quantity of carbonic acid exhaled to be double that eliminated at a temperature of from 59° to 68°.

Animals with active respiratory movements, rapid capillary circulation, and blood rich in red lobules—such as birds, hyenas, tigers, &c.—resent in their tissues only a very trifling proportion of fatty matters. If such animals be prevented from moving about, the fat will be found to accumulate in their tissues. We learn from the experiments of Treviranus, that cold-blooded animals consume ten times less oxygen in proportion to their weight than mammiferous animals, and nineteen times less than birds.

Boussingault made a great many experiments in a view to establish, by comparing the composition of the food with that of the excrements, whether nitrogen is exhaled in the respiration of the granivora; the results obtained led this observer to the following conclusions:—A turtle-dove consumes in twenty-four hours, 5.1 of carbon; it emits in the same space of time 18.7 grammes of carbonic acid (9.441 litres), and 0.16 gramme of nitrogen (0.126 litre). It consumes 0.7 gramme of hydrogen per diem. From these data, we find that a turtle-dove weighing 187 grammes, and breathing freely at a temperature of from 46° to 50° Fahrenheit, is able—in consuming 5.1 grammes of carbon, and 0.07 gramme of hydrogen—to generate the amount of heat necessary to maintain its body at a temperature of

from 105°·8 to 107°·6 Fahrenheit; and this whilst exhaling, moreover, about three grammes of water through the lungs and skin.

It is unquestionable, therefore, that the animal organism is a real apparatus for combustion, in which carbon is constantly consumed and converted into carbonic acid, and heat generated. It is perfectly clear that the source of animal heat lies solely in the chemical reactions of respiration and nutrition, and, more particularly, in the combination of the carbon with the oxygen.

Dulong, Despretz, and others, have endeavoured to ascertain whether the amount of heat generated by animals corresponds in direct ratio to the amount of carbon and hydrogen consumed. If the carbonic acid and the water exhaled by the animal are the products of the combustion of carbon and hydrogen, the heat generated by the animal ought (according to the reasoning of some philosophers) to be equal to that which the combustion of the same quantities of carbon and hydrogen in the open air would generate.

The amount of heat generated by an animal may be determined by that which the animal imparts to surrounding objects—to water, for instance. Dulong and Despretz placed animals in an apparatus constructed for the purpose; they measured the amount of carbonic acid and water exhaled by the animal, and noted the temperature acquired by the surrounding water. They found that the combustion of the carbon and hydrogen, as deduced from the amount of carbonic acid and water evolved, would only account for eighty or ninety per cent. of the heat generated by the animal. Certain manuscript notes found after Dulong's death show, however, that this celebrated physiologist had subsequently made a series of further experiments, of which the results proved that the amount of heat generated by the combustion of the hydrogen in the animal organism is much more considerable than he himself and Despretz had at first calculated. The results of these latter experiments of Dulong have been fully corroborated and confirmed by those obtained by Fabre and Silbermann. If we adopt the new figure for the heat generated by the combustion of hydrogen, deduced from the corresponding results of Dulong's, Fabre's, and Silbermann's experiments, we find that more heat is actually evolved by the animal than is marked by the calorimeter.

But, even supposing the contrary to be the case, it would be easy to account for the excess of heat marked by the calorimeter without having recourse to the assumption of a particular power or vital property as an additional source of heat. Let us simply reflect that the temperature of the animal placed in the calorimeter is invariably higher than that of the surrounding water, and that, consequently, the animal cools during the experiment. In fact, Despretz found in his numerous experiments that the excess of heat marked by the calorimeter is the greater the younger the animal, and the higher its temperature. We know, moreover, by Edwards' experiments, that the temperature of young animals sinks much more rapidly than that of grown-up animals.

Besides, it seems very doubtful whether ordinary combustion effected in a calorimeter can be considered an exact type of the combusive process that may take place in the organism; and we think the notion which would select, amidst the numerous chemical reactions occurring in the organism, a single one as the exclusive source of animal heat cannot well be sustained.

And, indeed, if we look somewhat more closely into the subject, we cannot help observing that the carbonic acid with which the venous blood is charged—and which is unquestionably a product of the combination of the atmospheric oxygen with the carbon of the organic elements of the divers tissues—does not proceed from free carbon, but from the various compounds of carbon present in these tissues; and these compounds are, as yet, but very imperfectly known to us.

Now, Dulong's experiments have placed it beyond doubt that the combustion of bodies in a state of combination fails to generate the same amount of heat as the combustion of the same bodies in the free state.

It would be difficult to reconcile the results of Andral's and Gavarret's recent experiments on the exhalation of carbonic acid in the respiration of man, with the notion that animal heat is produced exclusively and alone by the chemical action of the carbon and hydrogen with the oxygen. The very extensive and, to all appearance, precise experiments of these distinguished physiologists show that the quantity of carbonic acid exhaled in respiration may vary greatly with the sex, age, and peculiar physiological disposition of the individual—the difference lying between the figures 5 and 11·4, which express in grammes the amount of carbon that concurs in the formation of the carbonic acid exhaled in the space of one hour. The former of the two figures was found in the case of a child eight years old, the latter in that of a young man of twenty-six. It ought to be borne in mind here, that the temperature of children being notably higher than that of adults, and the mass of surrounding objects to which heat is imparted being greater with adults than with children, the loss of heat must be proportionally greater in the case of adults than in that of children.

Andral and Gavarret found, also, that the period of puberty in woman does not increase the amount of carbonic acid exhaled, but that this exhalation becomes more active when age or other causes put a stop to menstruation.

Notwithstanding this, no sensible difference of temperature is observed in the body of a woman neither before nor after, nor during menstruation, nor during pregnancy. We know, moreover, that certain diseases are attended with a rapid lowering of the temperature of the body, whilst others exhibit among their symptoms a very considerable elevation of temperature throughout the whole body; and yet in neither case do we ob-

serve a corresponding variation in the respiratory function.

To sum up: In the actual state of our physico-chemical knowledge, we must assume that the animal heat is generated by the chemical actions occurring in the organism during the transformation of the tissues, under the influence of the atmospheric oxygen; that the combustion of carbon and of hydrogen is the principal, but not the only and exclusive, source of the heat generated; and that we do not possess experimental data sufficient to enable us to discover and establish the exact relation between the heat generated by the chemical reactions occurring in the living organism, and that generated by those chemical reactions which we are able to produce in our apparatus.

The heat generated during the germination of vegetables has its source likewise in a chemical action, viz., the combination of oxygen with the carbon of the germinating grain. We know that germination is attended with absorption of oxygen and evolution of carbonic acid; and also that diastase converts starch into dextrine and sugar, which upon continued fermentation is further converted into alcohol, with disengagement of carbonic acid. The evolution of heat which attends the fecundation of plants may be explained upon the same principle.

DUMAS ON ORGANIC CHEMISTRY.

No. XXVI.

(Continued from page 429.)

ON THE MILK—(continued).

Now that we know the chemical nature of the milk, and the varied circumstances which influence its production, we shall proceed to regard it in an economical point of view, indicating, in the first place, the usual quantity of milk which is furnished by the cow in the normal state. The following table gives us, on this point, the result of various observations made in different countries.

Table of the Quantity of Milk which may be produced by the Cow.

Localities.	Authorities.	High Cow	Hay consumed daily.	Milk produced annually.	Milk given daily.	Observations.
France.—La Feuillasse (Ain)	Perrault de Jotemps	400	12·5	1700	4·7	Kept in cowhouse.
• Lompries (Ain)	D'Angleville ..	275	6·3	915	2·5	Do. do.
Roville (Meurthe)	De Dombasle ..		10·0	1416	3·4	Do. do.

Paris and its environs	Quévenne, <i>Ann. sur le Lait</i> .				11·0	

In M. Le Bel's experiments, he measured, night and morning, the milk given by each cow. Seven cows, each consuming fifteen kilogrammes of hay, or an equivalent to the above in green fodder, furnished, in the course of a year, 17576·5 litres of milk, which were distributed as in the opposite table:—

At a mean calculation, each of the above cows produced, in the year, 2511 litres of milk; the number of milking days was, for each cow, 302½. The daily average for each, therefore, according to the foregoing estimate, was 8·3 litres. This quantity is, however, reduced to 6·8 litres, if we make no allowance for the days of respite, and thus take the mean of the entire year.

All the observations made tend to prove that the quantity of milk secreted diminishes in proportion as we recede from the period of parturition.

In measuring the quantity of milk, given by a cow, from the moment of its calving up to the time at which it ceased to yield any more of this

Months.	Milk yielded per month.	No. of days in which milk was given (for the 7 cows).	Daily product (per head).
January ...	1063·0	186	5·7
February ...	759·0	158	4·8
March	759·0	155	4·9
April	942·5	138	6·7
May	1436·0	155	9·3
June	2117·5	190	11·1
July	2375·0	195	12·2
August ...	2080·5	186	12·8
September ..	1769·0	180	9·8
October ...	1490·5	184	8·1
November ..	1443·5	200	7·2
December ..	1341·0	191	7·0
Total.	17576·5	118	

secretion, it was found that it produced between these two periods 16·049 litres, in 2167 days' milking; this gives a mean of 7·4 litres per day.

A precisely analogous result was attained with another cow, which furnished 2293 litres in 310 days; the mean product of each day was, consequently, 7·4 litres.

It is often of great importance to determine the quantity of butter contained in the milk. The data which we possess as to the proportion of butter and cheese in this fluid are, however, of a very unfixed character. M. Boussingault gives us the following, obtained under his own eyes: One hundred kils. of milk furnished:—

Cream	15k.60
White cheesy matter ..	8. 93
Whey	75. 47

100. 00

The 15 kils. of cream gave on churning—
Butter 3.33, per cent. 21.2

Buttermilk ..	12.27
---------------	-------

White cheesy matter	8k.93
Butter	3p.33
Butter-milk	12.27
Whey	75.47

100. 00

By examining the milk drawn at different periods of the year, the same observer found that 16.391 kils. of this fluid produced 491 kils. of fresh butter, or three per cent.

M. Quévenne obtains numbers slightly different: he agitated 54k-633 of cream in a churn, the temperature being at about 20° C.; this quantity yielded 15k-100 of butter of a good quality, and 39 kils. of buttermilk, having a density of 1.031. The foregoing butter furnished, on analysis—

Pure butter	77.50	per cent.
Caseum	1.60	"
Water	20.90	"

100.00

The buttermilk contained—

	In the decilitre.	In the litre
Butter	0g. 25	2g. 50
Caseum	3. 92	39. 20
Sugar of milk, ex- tractive matters in pretty abun- dant quantity, and salts	5. 30	53. 00
	<hr/> 11. 07	110g. 70
Water	91. 95	

103g.00

We see, then, that in 15k.100 of crude butter thus obtained, corresponding to 11k.713 of pure butter, we lose 39 times 21g.5—that is to say, 838g.5 of pure butter. Besides the loss just stated, M. Quévenne has pointed out another—namely, the butter which remains in the milk after its being thoroughly deprived of its cream; this he values at 2g.30 per *litre*.

In addition to the foregoing data, we will give the analysis of skimmed milk made by Berzelius :—

Water	928.75
Caseum and butter	26.00
Sugar of milk	35.00
Alcoholic extract and lactates	6.00
Chloride of potassium	1.70
Alkaline phosphate	0.25
Phosphate of lime, lime combined with caseum, magnesia, and traces of iron	2.30

1000.00

The cream, analyzed by the same chemist, produced—

Butter obtained by churning

Caseine procured by the coagulation of

the buttermilk

Serum
---------------	----

100.0

The salts, which M. Berzélius found in the milk of the cow, were chiefly, as we see, those of potass. But we have already stated that these

salts may vary according to the nature of the aliments. M. Haidlen gives the following analysis as that of the salts of normal milk :—

Phosphate of lime	..	0.231	0.344
„ magnesia	..	0.042	0.061
„ iron	..	0.007	0.007
Chloride of potassium	..	0.144	0.183
„ sodium	..	0.024	0.034
Soda	..	0.042	0.045

0.490 0.677

MM. Pfaff and Schwartz have found that 1000 parts of milk furnished 3.742 of ashes composed of:—

Phosphate of lime	1.805
Ditto of magnesia	0.170
Ditto of iron	0.032
Ditto of soda	0.225
Chloride of calcium	1.350
Soda	0.115

3.697

The earthy phosphates are drawn along by the caseum in its coagulation. The concentrated acids remove them from it. The caseum may contain as much as six or seven per cent. of these salts.

Milk entering largely into the diet of the inhabitants of towns, and passing through many hands before arriving at those of the consumer, is often the object of frauds, of which the most common consists in removing a certain proportion of the cream, and adding water to the milk, thus impoverishing.

Albuminous substances, such as the serum of blood or of eggs, which are added to the milk for the purpose of augmenting its density, are at once discovered by applying heat, which coagulates the albuminous matter. We have, however, seen that, at times, the milk may itself be albuminous.

Gummy matters give a degree of viscosity to the milk; to discover them, we must have recourse to a somewhat delicate analysis. But, according to M. Quévenne, it requires not less than 90 grammes of gum arabic to give to a litre of water a specific gravity of 1.030—the ordinary density of the milk of Paris; this fraud cannot, therefore, offer any real advantage to the practitioner.

When pure milk has been coagulated by acetic acid, and a little alcohol is poured upon the filtered serum, we have formed abundant, light flakes, of a bluish-white colour and transparent. If we make the same experiment with milk which contains gum arabic, the precipitate will be more abundant, of a dull white, and opaque.

Milk has sometimes been adulterated with gum tragacanth; but this substance, in the proportion in which it can be employed, does not alter its density. Should it, however, have been added, the milk, on being treated as in the former

instance, will furnish, with alcohol, a light flaky precipitate, which may be drawn out in long threads.

To discover dextrine in milk, we should throw down the caseum by acetic acid, precipitate the filtered serum by alcohol, and treat the precipitated matter with a little water, which dissolves the dextrine. The polariscope will, in like manner, serve to detect this fraud.

Sugar, when added to milk in the proportion of one per cent., gives to it an unnaturally sweet taste; in the proportion of two per cent., the fraud is at once recognisable by the tongue. Glucose, being less sweet, would be more difficult of discovery.] But, in either case, a little beer-yeast, when added to the milk, will, in a short time, excite the alcoholic fermentation; whereas we know that the sugar of milk ferments with great difficulty.

We may easily detect the presence of fecula, or the infusions of amylaceous matters, as rice or oatmeal, by rendering the milk slightly acid, and then adding to it tincture of iodine.

The emulsions of oleaginous seeds would soon betray themselves by the taste or odour which they would communicate to the milk, and also by the debris of the cellular tissue of the seeds themselves.

It has been imagined by many that, in large cities, like Paris, the milk has at times been adulterated with emulsions made of the cerebral substance of various animals; such a fraud would, however, at once be revealed by the microscope.

Undoubtedly, the most common manoeuvre consists in removing the cream from the milk, and then adding a certain quantity of water. The milk, when thus diluted, besides being less nutritive than in its pure state, becomes readily curdled and sour, and keeps a much shorter time.

As, ordinarily, the cream entirely separates at the end of twenty-four hours, we may judge, up to a certain point, of the quality of the milk, by measuring the quantity of the cream. This means, long since employed in England, has been recently introduced into France. We are to take a graduated measure, pour into it the milk, and then set it aside; if it be of good quality, we usually obtain as much as 8 to 8½ per cent. of cream, when compared to the volume of milk employed. We must, however, acknowledge that this proceeding furnishes but uncertain data: for, even with pure milk, the volume of cream separated varies according to the temperature to which the milk is exposed. It is greatest at a temperature which does not exceed 8° C. At from 12° to 20°, according to M. Quévenne, the volume of cream appears to remain pretty stationary.

The following table presents us, at one view, with the results of all the analyses which have been made on the different kinds of milk.

Milk.	Composition of the Milk.					Remarks.	Analysers.
	Casein, Albumen, and insoluble salts.	Fatty matters.	Sugar of milk, and soluble salts.	Water.	Dry matter in 100 parts of milk.		
Cow ..	3.6	4.0	5.0	87.4	12.6	Mean of 12 analyses. Bechelbronn.	Le Bel & Bousinval.
Do. ..	3.8	3.5	6.1	86.6	13.4	Mean of 6 analyses, in environs of Paris.	Quérvenne.
Do. ..	4.5	3.1	5.4	87.0	13.0	Do. do.	Henri and Chevallier.
Do. ..	5.6	3.6	4.0	86.8	13.2	Do. do.	Lecanu.
Do. ..	5.1	3.0	4.6	87.3	12.7	Milk from environs of Glessen.	Haidlen.
Ass ..	1.7	1.4	6.4	90.5	9.5	Mean of 5 analyses.	Pelgot.
Woman	3.1	3.1	4.3	89.2	10.8	Of good quality.	Haidlen.
Do. ..	2.7	1.3	3.2	92.8	7.2	Of middling quality.	Haidlen.
Do. ..	2.2	5.1	7.8	85.8	14.1	Mean of 3 analyses.	Payen.
Do. ..	3.8	2.5	4.8	88.4	11.6	Mean of 14 analyses.	F. Simon
Goat ..	9.0	4.5	4.5	82.0	18.0		
			Extractive matter and salts.				
Bitch ..	16.0	14.75	2.95	66.3	33.7	Mean of 2 analyses; traces of sugar of milk.	F. Simon.
			Sugar of milk, and soluble salts.				
Mare ..	1.6	A little.	8.75	89.63	10.37	The weight of the cream in this milk was only 0.80 per cent.	Stipriann, Luitens, and Bondt.
			Sugar, extractive matter, and salts				
Cow ..	7.0	3.9	3.5	85.9	14.1	Mean of 2 analyses.	F. Simon.
Do. ...	6.8	3.8	3.6	85.7	13.9	Do.	Hertberger.
Goat ..	4.5	4.1	5.8	85.6	14.4	One analysis.	Payen.

In a memoir published on the fattening of animals, and on the formation of the milk, by MM. Boussingault, Payen, and myself, we showed that a milk cow can extract, for the benefit of man, from a given pasturage, a quantity of alimentary matter more than double that drawn from it by a fattening ox; and we further drew a conclusion, that the establishment of the commerce in milk upon a system capable of inspiring general confidence, is a subject in the highest degree deserving the attention of the public administration.

The milk of the cow is liable to various alterations, and offers, in such case, remarkable differences both in its qualities and in its composition. Among these alterations, some depend on an affection of the animal itself, while others manifest themselves in the milk, only after twenty-four or forty-eight hours' rest.

Cows are subject to a disease known in France by the name of *ecolite*; the milk which they furnish in this state is usually less fluid than natural; when examined by the microscope, it invariably presents adherent muriform globules, sometimes mucous, at other times purulent. If treated by ammonia, it becomes viscous. It quickly presents marked phenomena of putrefaction. Sometimes, the pus gives to it so great a degree of fetidity that all examination becomes useless, and it should then be wholly rejected from consumption. The prevalence of this disease around Paris does not seem to prevent our milkmen sending their commodity to market; nor have we known any serious injury done to the public health in consequence thereof.

M. F. Simon made a comparative analysis of two portions of cow's milk taken from different teats of the same udder—the one of which was sound, the other covered with various pustules. The milk drawn from the diseased teat was strongly alkaline, and possessed a saline taste; when examined by the microscope, he discovered in it purulent or mucous globules; caustic ammonia rendered it gelatinous. The milk proceeding from the sound teat had a feeble acid reaction.

The following was the composition of these two kinds of milk:—

	Milk of the sound teat.	Milk of diseased teat.
Water	91.21	93.51

M. Herberger examined the milk given by cows affected with disease of the hoof. In the first stage of this disease, the milk was alkaline, and rennet coagulated it but imperfectly; the butyrous globules did not present their usual clear outlines, but seemed to be confounded together. In the second stage, also, the milk was but incompletely coagulated by rennet; it was viscous and had a putrid and disagreeable colour and taste. It contained carbonate of ammonia. The fixed salts were found there in double the proportion to what we observe in normal milk. The following are the results of his analyses:—

	First stage of disease.	Second stage.	Sound milk.
Water	86.90	87.24	87.48
Solid residue ..	13.10	12.76	12.52

Density	1.0336	1.0330	1.0331

The milk arising from healthy animals or occasionally presents, after the lapse of twenty-four or forty-eight hours, certain modifications in its colour, which passes to blue; sometimes, this change is not shown until after the lapse of several

days. Ancient observers had already directed attention to this fact, which M. Baillieu has likewise remarked in the arrondissements of Havre and d'Yvetot. The blue coloration appears at first in isolated patches, in which some believe to have noticed tufts of *byssus*, or hair.

The milk is subject to another alteration of the same kind, but, in place of becoming blue, it here turns yellow.

M. F. Fuchs has paid great attention to these phenomena: he has observed that the blue milk contains a particular species of *infusoria*, to which he has given the name of *ribrio cyanogenus*. This insect appears to be itself colourless; but we can turn every kind of milk blue by placing it in contact with it. These animalcula may be generated in an infusion of mallows, and they will thus give to it a pale blue colour. We may preserve them for a long time in this liquor.

The yellow milk contains the *ribrio xanthogenus*—an insect which behaves precisely as the foregoing. Sometimes, also, we find it in the blue milk.

Occasionally, we see in large cowhouses, where the same kind of regimen is used throughout, that the milk of certain animals alone presents these phenomena of coloration. The employment of chloride of sodium appears to obviate the particular state which gives rise to these insects.

ON THE PHYSIOLOGICAL AND PATHOLOGICAL CAUSES OF SUDDEN DEATH IN CONNECTION WITH THE VASCULAR OR CIRCULATORY SYSTEM.

By M. W. HILLES, Esq.

(Continued from p. 333.)

Having considered the physiological and pathological phenomena, apparent in cases of sudden death, produced by a deranged state of one or other of the two great centres of life, namely, *respiration* and *circulation*, I shall proceed to inquire into those cases of sudden death which appear to be produced by a destruction of the influence of the third great centre of life—the *nervous system*.

This is, indeed, the most important division of our subject, as the nervous influence is so extensive, and so necessary to all the functions of life—both those which minister to the physical wants of the individual, and those which produce the development of his moral qualities—that it may be regarded as universal, and as well taking its share in the action of the two great centres of life already treated of, as in the maintenance of that over which it immediately presides.

This extensive influence of the nervous system, in all the vital actions, would render such an inquiry as the present extremely complicated and unsatisfactory, if we had not adopted a certain division of the subject which, although, strictly speaking, it may be somewhat artificial, is sufficiently based on natural laws to justify its adoption, and sanction the conclusions derived therefrom.

Such a division is necessary in all similar inquiries: for the vital actions are so mutually dependent on each other, and the vital phenomena so closely linked together, that it is impossible to regard any one without some reference to the other. Respiration, for example, could not be carried on without the agency of the nerves, in causing the contraction of the respiratory muscles, and influencing the change of the venous into arterial blood, in the air-cells of the lungs; nor could the circulation be continued, unless the heart and bloodvessels received their due supply of influence from the nerves.

I shall confine my observations, in the present inquiry, to those cases of sudden death in which the destruction of the nervous influence appears as the evident cause of the immediate suspension of the vital powers.

To the perfect organization of his nervous system, man is indebted for his superiority in the natural world; not only does it, as in the lower tribes of animals, preside over the functions and offices which contribute to the supply of his physical wants, and to the preservation of his material being, but it also endows him with a superiority of reasoning power which places him, in the scale of the animal creation, immeasurably beyond all other living beings.

Numbers surpass him in the power of their muscles, or in the strength of their bones; many excel him in all those acts which are produced by the mechanical exercise of their physical abilities; but in one does he surpass them—one only, and yet one sufficient to set at nought the swift flight of the rapid eagle, the towering strength of the majestic lion, or the overwhelming force of the monstrous whale: that one is REASON. Confiding in this, and armed with the weapons she has already devised for his use, he faces the lion in his den, the monster of the deep in the recesses of the frozen seas, and stops the soaring powers of the king of birds.

There can be no doubt that the *intellect* or *reasoning powers* of man reside in the nervous system, and depend as completely on the organization and perfection of this, as any one of the more simple acts of the animal depends upon the integrity of the structures engaged in its execution.

Many are inclined to attribute this superiority of the reasoning faculties of man to a spiritual cause, and reject the doctrine of the connection between mind and matter as untenable and dangerous. But such are unquestionably in error: all the phenomena of life and disease prove, beyond a doubt, that the mind is intimately connected with the material structure of the brain; they increase, flourish, and perish together: what tends to the development of the one, promotes the growth of the other; what annihilates this, consigns that to destruction.

It would be out of place, here, to enter fully into the discussion of this subject; but there is no difficulty in bringing forward numerous proofs of the opinion that the intellectual perfection depends upon the physical organization.

Some learned writers have, with great force but very little ability, opposed the dissemination of such an opinion, as opposed to the spiritual existence of man; but there is no reason why the *spirit* or *soul* of man, and his *intellect* or *mind*, should be regarded as one and the same. The spirit or soul may be, and I believe is, something added to our material being, but of which we have no distinct knowledge; the presence of which we may believe, but cannot demonstrate. What the nature of its connection may be, with our material organization, is far beyond the reach of our inquiries, and rather forbids than encourages us to analyze its being, or to attempt to fix its seat.

The absurd doctrines of modern times should not, must not, compel us to shut our eyes against facts, and refuse the admission of truths beyond question. We need not fear such investigation; nay, advance only leads us the more to contemplate the greatness of our Creator with respect, and to convince us of the littleness of our intellect compared with His wisdom.

The untutored savage may fall down before the spirit of the winds or the genius of the elements, and witness his god in the raging of the furious storm, where all seems destruction, and threatens annihilation; but the philosopher and physiologist behold His presence revealed in the perfection, and greatness, and beauty of His works; acknowledges His power with admiration even where their intellect fails to follow, and cease only to admire when they no longer continue to exist.

I have been led to this, which may be considered as a digression, by the circumstance that many cases of sudden death occur from impressions made on the moral feelings, as well as on the physical functions, through the agency of the nervous system.

The impression, in such cases, is made on the

feeling or passion affected, through one or more of the external senses, most frequently the eye or ear, whence it is carried to the seat or organ of the feeling or passion influenced, where the impression acts so injuriously as to destroy life and, in other cases, impair reason.

Fear, anger, and many other passions of the human breast, have been known to cause sudden death. How are we to explain such an occurrence, except through the agency of the nervous system? The feelings or passions must reside in some part of the frame, and all observation leads us to refer them to the nervous centre, rather than to any other part of the human structure. All the other functions minister to the intellectuality, the moral essence of the individual; this, in turn, presides over and regulates these, and so controls the actions of man as to lead to his safety and preservation.

I cannot understand, therefore, why reason should be assigned an immaterial nature, or why it should be set apart as the spirit or soul of man, more than any other of the apparently immaterial essences forming the passions which link him to the external world; especially as this is equally affected by those material changes which take place in the human organization, as any other of the properties with which man is endowed.

The nervous system, then, presides over all the actions of the animal economy, whether internal or external.

It controls the growth and nourishment of the corporeal structures.

It regulates the physical functions of man, and influences the several secretions.

It is essentially necessary to the perfection of the respiratory and circulatory functions—two of the great centres of life.

It connects man with the external world through the agency of the senses.

And, finally, it is the seat of the moral qualities of which man is possessed, and which enable him to perceive, feel, judge, and reason.

We need not be surprised, therefore, at the numerous diseases produced by derangement of the nervous system, or any part thereof, or the sudden fatality which attends more violent impressions made upon it.

How these latter act so as to produce a rapidly-fatal effect is difficult to decide; we can only conjecture that the impression so made deranges in some manner the nervous current, and thus tends to a suspension and ultimate destruction of the nervous influence, and the remaining functions on which life depends.

That such is the correct explanation of the phenomena observed in such cases is supported by the swooning or fainting of persons on the receipt of painful intelligence or of serious injury. Here an impression is made sufficient to produce a temporary suspension of the nervous influence and the remaining vital functions; it requires but a more powerful impression to cause similar but permanent results.

It is not necessary that any lesion or disorganization of tissue should exist in such cases; derangement of function is sufficient to produce the fatal termination.

But in what consists this functional derangement; how or by what means it is produced; how the nervous influence is checked, or altered, or perverted, so as to lead to a destruction of life, are matters wholly beyond our examination at present, as we are still ignorant of the real nature of the nervous fluid, or other agent by which it operates, and of that life which falls a sacrifice to its derangement or destruction.

Diligent investigation may and will, doubtless, disclose many things of which we are at present ignorant; but I fear much that we shall never fully comprehend the intricate phenomena which the agency of the nervous system and the vital principle presents.

In order to explain more clearly the mode in which impressions are made on the nervous system, so as to induce a suddenly-fatal termination, it will be necessary to recur to mind the anatomy of this part of the human frame.

The nervous system is evidently composed of divisions, namely, the cerebro-spinal and the sympathetic: the former, as its name implies, embracing the cerebral mass, or brain, and the spinal marrow, together with the several nerves proceeding from both these structures.

The cerebral mass, or brain, consists of two principal portions, the cerebrum and cerebellum. The former of these is much the larger of the two, and contains numerous bodies, varying both as to size and shape, all of which have their peculiar offices to perform, both as isolated structures and as part of the general mass.

The cerebrum, properly so called, presides over all those actions and functions which connect man with the external world. Thus, for example, proceed from it all the nerves of special senses, viz., the first, or olfactory, in which the sense of smell resides; the second, or optic, which form the retina, and are the seat of vision; the fifth, which supply the nerves of taste to the tongue, and the portio mollis or acoustic portion of the seventh, to supply the organ of hearing. The only exception to this is in the sense of touch, which is supplied to all surfaces chiefly by the spinal nerves. This may be and is, no doubt, owing to this sense being less connected with the intellectuality of the individual than the other senses, which derive their supply of nerves directly from the cerebral mass.

The remaining cerebral nerves, viz., the third, fourth, part of the fifth, the sixth, and the portio dura of the seventh, are distributed to supply the special organs of sense, some with motion, others with sensibility, and seem to be derived from this portion of the cerebral mass, in order that they may be the more intimately connected with the special nerves of sense supplying these organs, and thus maintain that sympathy of action so essentially necessary.

Sir Charles Bell's theory (a) regarding the use of the portio dura being associated with the respiratory nerves, is opposed to this view; but more recent investigation has called his theory into question, and has thrown considerable doubt on the true use of this nerve. That it is associated with the special organs of sense, in its actions, is evident from its origin, course, and distribution.

The eighth and ninth nerves are not, correctly speaking, cerebral nerves, although classed as such; they more properly belong to the spinal nerves, as they arise from the upper extremity of the spinal marrow, the medulla oblongata.

But the great office of the cerebrum is to contribute to the intellectuality of the individual; it supplies man with all those faculties which enable him to receive impressions from the external world, whether these are applied physically or morally, through the agency of the senses; and, subsequently, to reflect, judge, and act.

It is the seat of Reason—the centre of that Mind to which he is indebted for his superiority over all other animals—which raises him above the brute creation, and links him more closely to the Creator.

All observation tends to this conclusion: its comparatively greater size in man—in the adult than in the young—in the educated than in the ignorant—in the inhabitant of civilized countries than in the uninstructed denizen of savage wilds—in the enlightened sage than in the untutored child of nature—in the individual marked by the possession of great intellectual faculties than in him who is deficient in mental qualifications.

Disease is equally powerful in support of these opinions. The pressure of a piece of bone, or a clot of blood, or other extraneous body, destroys the mental faculties; inflammation of the brain renders the man of reason a violent idiot; disorganization, abscesses, &c., reduce the talented statesman, or the great writer, or the profound philosopher, to a driveller and a show.

(a) "The Nervous System of the Human Body," by Sir C. Bell, K.G.H., &c.; p. 54. Edinburgh: 1836.

It is in vain for those who consider themselves natural theologians (a), but who are, in my estimation, most unnatural theologians, to endeavour to support their opinions in opposition to a host of facts; their attempts to do so rather injure than serve the cause they undertake.

If the mind be dependent on material structure, it by no means follows that the soul or spirit is equally so; this is spiritual and eternal, that material and perishable; of the former we have physical evidence, of the latter, none, save that which is derived from the sacred and other writings of antiquity.

The cerebellum seems to preside more over the instinctive faculties or animal instincts of man, and is especially connected with the sensibility of the individual, and receives from, or contributes to, the spinal marrow the continuations of the corpora testiformia, from which the sensitive roots of the spinal nerves arise.

It is intimately connected with the animal life of the person; hence injuries, accidents, &c., to this portion of the brain are much more dangerous than those affecting the cerebrum.

The spinal marrow appears to be a prolongation, from the cerebrum and cerebellum, into the spinal canal, and does not possess, as it is generally supposed, any power of action in man independent of them. In some of the lower tribes of animals it is otherwise.

The cerebro-spinal nerves act as the chords which convey the necessary impressions to and from the great nervous centre, the brain.

The sympathetic forms a distinct system of nervous influence, although connected with the preceding by numerous anastomosing filaments.

Almost exclusively confined to the trunk, it presides over the great functions of respiration and circulation, on which life depends, and also over those of digestion, secretion, &c.

It has little connection with the brain, and is, therefore, but little related to the intellectuality of the individual. Nature has assigned to it the office of regulating the functions just stated, which she has thus taken, as it were, from the control of the intellect of the person, placing them under the superintendence of a distinctly independent nervous system, which sustains these functions in action without the concurrence of the will or senses of the individual.

The sympathetic system thus presides over the organic functions, or, as they may be considered, the vegetative life, as distinct from the animal life of the species.

This is a wise provision of nature, as thereby the functions on which the sustentation of the frame depends are independent of the condition of the intellectual organs, and continue their action when these are otherwise engaged or sunk to rest, as in sleep, stupor, &c.

This division of the nervous system enables us to understand more completely the *modus operandi* of injuries, disease, or other injurious agents, in producing a fatal termination, according as one or other, or all, of these various portions of the nervous system may be affected.

In order to simplify, as much as possible, the consideration of our subject, I shall divide it, as I have previously done, when considering the causes of sudden death in connection with a deranged state of the respiratory and circulatory functions, into two parts, namely.

FRACTURE OF THE CERVIX FEMORIS AT AN EARLY AGE.

By C. H. HALLETT, Esq., University of Edinburgh.

The following instance of fracture of the cervix femoris within the capsular ligament of the hip-joint is chiefly interesting on account of the age

(a) We have, therefore, evidence of the strictest kind, induction of facts the most precise and unerring, to justify the conclusion that the mind exists, and is different from, and independent of, matter altogether.—"A Discourse on Natural Theology," p. 107. By Henry Lord Brougham, F.R.S., &c. London: 1835.

of the individual, but is also worthy of notice on account of the remarkable changes which had taken place in and around the fractured portions of the neck of the femur, and which must undoubtedly have allowed the individual the full and perfect use of the limb, as far as progression is concerned.

Jane Mason, aged twenty-three, stated in the medical certificate to have died of paralysis, was brought to the dissecting-room of this university in the beginning of May, 1846, for the use of the practical anatomist. My attention was directed to the condition of the body before the dissections were commenced, in consequence of the shrunken appearance of the whole of the right half of the body, which strikingly evidenced that the paralytic affection had existed for a considerable period of time before the death of the individual. The superior extremity was diminished considerably in size, its circumference being scarcely one half of that of the opposite and well-formed limb. The fingers and wrist were permanently flexed and distorted. The lower extremity also bore evident marks of the prolonged existence and of the effects of the paralysis. The whole limb was much decreased in bulk; and the ankle-joint and toes were in much the same condition as the wrist and fingers. The affected leg was also observed to be shorter by about two inches than the other. This shortening I at first referred to the condition of the foot and leg, but subsequent dissection showed it to be caused, at least partly, by changes which had been induced in and about the neck of the femur, after fracture within the capsular ligament. As soon as the fracture was detected I examined the parts which had been removed from the trunk, and found they exhibited great alterations both in their form and in their disposition—alterations which differed somewhat from those usually found after similar lesions.

The upper and inner part of the shaft of the femur presented, between the greater and the lesser trochanters, a deep fossa passing from above obliquely downwards and inwards, wide and deeper below than above, and divided into two unequal portions by a slight ridge crossing it transversely. The portion below the ridge was covered with cartilage and a synovial membrane; the portion above afforded attachment to strong ligamentous fibres. The anterior lip of this fossa was smooth and somewhat convex. A little below and anterior to this fossa, a smaller one, also covered with cartilage and synovial membrane, existed; and above and posterior to it was another—the trochanteric fossa—separated from the large abnormal one by a projecting ridge of bone. The lesser trochanter was greatly enlarged, and presented an oblong smooth surface running obliquely downwards and forwards, which was tipped with cartilage. On the anterior and posterior intertrochanteric lines were a number of small irregular nodules of bone, which indicated an attempt at the enclosure of the fractured extremities of the neck of the femur in an osseous case. The surface of the neck immediately in front of the abnormal fossa also presented a development of osseous matter in the form of a thin plate elevated above the level of the neck. In all other respects but those mentioned the shaft and outer portion of the neck of the femur were normal. The alterations which had been induced in the head and, more especially, in the inner portion of the neck of the femur were even more considerable. The head had lost its spherical form, in consequence of the bulging backwards of the upper and posterior part of its circumference; of the removal of a portion of the lower and posterior part of the same, and of the development of a bony crest projecting from the centre of the head immediately above the fossa for the ligamentum teres, which divided the head into an anterior and a posterior segment. Only a small portion of the inner part of the neck existed as a *prismatic* process projecting outwards from the upper and outer part of the head. The upper surface of this part of the neck was convex; the anterior was slightly concave and smooth; the

posterior was also concave but irregular: both the latter were covered with cartilage. The remainder of the neck had been removed by the absorbents, its inner and lower part where it is continuous with the head of the bone being excavated into a deep fossa of a semilunar form, constricted in the centre, but expanded at either extremity.

The head and inner segment of the neck were applied and articulated to the shaft in a peculiar manner. The neck had been tilted upwards so as to bring the trochanter minor and the head of the femur in close apposition—the former occupying the fossa in the inner and lower part of the neck, the production of which might, therefore, be referred to the friction of the trochanter minor against it. The neck itself, or rather the anterior and posterior surfaces of the *prismatic* process which alone remained of it were lodged in the abnormal fossa in the shaft. There was thus a double locking of the shaft into the head and neck of the femur. The fractured extremities were retained in their position by ligamentous fibres, a strong band of which passed between the upper portion of the abnormal fossa in the shaft, to the upper surface of the neck, whilst others held the head to the trochanteric lines. The whole was enclosed within the capsular ligament of the hip-joint which was entire and presented no traces of having been ruptured at the time the neck of the femur was fractured.

There were two joints enclosed within the capsular ligament—the hip-joint and the abnormal one developed between the fractured extremities of the neck of the femur; for these were provided with cartilage and a distinct synovial membrane, which had secreted a large amount of a viscid serosity, which lubricated the parts. The motions permitted by the latter joint were very slight. Before the ligaments were divided, it was observed that motion of the inner segment downwards was entirely prevented by the upper fasciculus of ligamentous fibres, and by the trochanter minor, which acted as a buttress to sustain the head of the femur; and that lateral motion was permitted to a slight extent. From the nature of the changes which had occurred in the fractured extremities of the neck, and the manner in which they were adapted to each other, it will be seen that the individual must have been able to stand firmly in the erect posture on the injured limb, and must have had the use of the limb for the purposes of progression, although the gait would be necessarily unnatural in consequence of the shortening of the extremity. In the erect posture, the weight of the trunk would necessarily be transmitted directly from the head to the shaft of the femur, through the trochanter minor; the trochanter minor and the head of the femur would be retained in close contact, and prevented from separating by the weight of the trunk, and by the ligaments; and the greater the amount of pressure applied to the head of the femur, in the longitudinal axis of the bone, the more firmly would the trochanter minor and the head of the femur be locked together, and the more secure would be the column of support afforded by the extremity to the body. These conclusions, made at the time, can easily be proved on the dried bone in my possession.

The age of the individual is one of the most interesting points connected with the case. It is well known to the profession that fracture of the neck of the femur generally happens in persons advanced in life, and has seldom been met with in individuals below fifty years of age. Three cases have been recorded in this country in which it happened before that period: one of these was seen by Sir A. Cooper, in a patient aged thirty-eight; another is spoken of in his work on Fractures and Dislocations, as having been shown him by Mr. Herbert Mayo, without the age of the individual being mentioned; and the third occurred to Mr. Stanley, in a boy aged eighteen. In my own case, which makes the fourth, the individual was aged twenty-three at the time she died. The precise time at which

the bone was fractured could not be ascertained, but I am led to believe it must have taken place a considerable period of time before she died; that it must have occurred before the limb had commenced wasting away under the paralysis: for it is difficult to suppose that reparative action, specially such as rendered the limb fit for progression, could have been set up and carried on in one part of the limb whilst the remainder of the extremity and indeed the whole of that side of the body were undergoing great changes from want or deficiency of assimilative power, and were being rendered totally useless to the individual. I have been unable to procure any information respecting the history of the woman, and am therefore reluctantly obliged to leave the case in an imperfect state.

Before leaving this case, it may not be uninteresting to mention one circumstance unconnected with the fracture, but probably connected with the paralysis. It was discovered during the dissection of the head and neck, that the "left" internal carotid artery was completely obliterated (apparently by inflammation), and reduced to a thin fibrous cord from the point of division of the common carotid to its termination by the side of the sella turcica; and that the right internal carotid was not enlarged, but, on the contrary, smaller than usual. May not the paralysis have been caused by a disturbance of the balance of the circulation within the cranium, induced by obliteration of one internal carotid artery, and a deficient collateral circulation, since no other lesion was detected during the dissection? If we connect this observation with others of a somewhat similar nature, made known to us of late years by different surgeons, namely, that paralysis of one side of the body sometimes ensues on ligation of the common carotid artery of the opposite side, we may be justified in answering the question in the affirmative.

The following plate is a faithful representation of the parts:—

- a. The fossa in the outer segment of the neck and shaft of the femur.
- b. The lower part of the fossa which received the inner segment of the cervix femoris.
- c. The upper part of the same which afforded attachment to a strong ligament.
- d. The trochanteric fossa.
- e. The trochanter minor, somewhat enlarged and covered in the recent state with cartilage.

The anterior trochanteric line is seen studded with numerous small spiculae and plates of bone.

f. The prismatic remnant of the inner segment of the neck of the femur.

g. That portion of it which afforded attachment to the strong ligament coming from the foramen (c).

h. The fossa in the head and inner segment of the neck of the femur which received the trochanter minor.

i. The ridge on the head of the femur, lodged in the recent state, in the notch in the acetabulum.

A SINGULAR CASE OF PARTIAL ERECTION OF THE PENIS.

By Dr. C. CLAY, Piccadilly, Manchester.

The following case is one of those that occasionally fall under the notice of a general practitioner, the cause for which defies all our attempts to unravel; and, in the treatment, former experience, however extensive, offers no guide of any certainty for its cure.

Mr. A. applied to me in the early part of May last: he appeared to be suffering much from nervous excitement; pale and emaciated; and, according to his own representations, had lost much of his physical powers, having been but a few months before a stout and vigorous constitution. He had been under the treatment of a very respectable practitioner for three months, that is, from the commencement of the attack to the present time, without the slightest relief; rather, on the contrary, he supposed himself going worse and tending, as he thought, to a hopeless condition. The symptoms now present were nearly the same as they had always been, and consisted of excruciating pain in the perineum, and about the neck of the bladder. The urethra, commencing about an inch, or from that to an inch and a quarter, from the usual orifice at the glans penis, and extending for an inch towards the base of the penis, was much hardened and thickened, and had the feel as though a broken piece of bougie or catheter had been left in it. When the penis was excited, the lower part, up to where the hardened urethra commenced, had a firm and vigorous erection, whilst the hardened portion and the remainder, including the glans penis, were not in the slightest degree affected by the erection of the lower part, and presented a most odd appearance. At the time of excitement the pains were most severe. I examined the penis carefully: first, however, I may mention, there was a malformation of the parts—the orifice of the urethra, instead of opening on the glans penis as usual, had its opening about an inch, or rather better, below the glans, and from that opening to the glans not the slightest remains of a urethral canal were observable; this feature, however, could not have influenced the case, as the gentleman was at least fifty years of age, and the father of a family. The hardening of the urethra commenced at the abnormal orifice. My patient was of strict moral character; had never had any gonorrhoeal affection, chancre, or bubo in his life. The calibre of the urethra was not in the least

diminished, as might have been expected by the hardening, for, on passing a large sized bougie down, not the slightest obstruction was offered to its progress. These, then, were the particulars of the case: the medical gentleman under whose care he had previously been had taken great trouble to ascertain the cause, but without success, and every mode of treatment adopted was equally unsuccessful. I felt not a little puzzled with the case, and determined to watch it carefully. I ordered a pill of ext. conii, gr. ij.; ext. hyoscy., gr. j.; hydr. chloridi, gr. ss., every night and morning, and passed a soft wax bougie smeared with ung. hydr. nit. every night. After continuing this for some days without any benefit resulting, I discontinued the use of the bougie, and submitted warm emollient fomentations to the parts; continued the pills, and gave also a mixture of liq. potassæ 3ij., with infus. gentianæ 3viij., a wine-glassful three times a day; still no good arose from it. It then occurred to me that it might possibly give way to an improved tone in the system; acting on this suggestion, I ordered the genitals to be rubbed gently with a mild soap liniment, and a quinine mixture, grs. xx. to the 3viij. mixture; the pills to be discontinued. I saw my patient the second day after the alteration of the medicine, and fancied I had found out the means of relief; my patient was equally elated; the pain had entirely ceased, and he fancied the erections were affecting the whole length of the penis more than for some time; we were doomed, however, to be disappointed. On the fourth day after the commencement of the quinine, the pains returned with greater violence, and the erections to their former state. I increased the dose, but with no better result; subsequently I tried plaisters made of the ext. conii round the relaxed portion of the penis, and along the course of the urethra, and to cover the perineum: still no benefit arose from them. My patient was now very low, excitable, and extremely irritable, and I saw the necessity of supporting the constitution, and again ordered the quinine mixture, with an expressed wish to see him the next day at an hour when I should have a little time to devote to him, when I determined in my own mind to have him stripped of his clothing, and make another careful examination. Accordingly he came next day prepared, and, when his clothes were removed, I observed a discoloured patch and slight depression of skin over the spinal lumbar region, and a similar patch in either groin; these patches were of the size of a crownpiece. I examined the parts carefully to find if any rupture showed itself, but observed no indication of anything of the kind. I remarked to my patient that I had been looking for a rupture, because I could not account for the discoloured patches, except by supposing he had worn a double truss; but, as there was no rupture, it must have arisen from some other cause. My patient now looked at me with some surprise, and stated that he had worn a double truss for near four months. I immediately asked for what purpose; when he stated that a friend and himself were taking a bath together, and his friend insisted that he must wear a double truss, because his groins were too full, and there was every fear that he would be at some future time ruptured, and that he ought to wear a truss as a preventive. I inquired if his last medical attendant knew of this, but he declared he had never mentioned it, as he thought one ailment was sufficient to trouble him with, and had, therefore, studiously avoided the matter. The whole mystery of the case now appeared to be cleared up; I felt no doubt that the mischievous symptoms arose, in the first place, from the pressure of a strong double truss, for the use of which there was not the slightest necessity. I, therefore, insisted on its being immediately laid aside; and without any other treatment, save the quinine mixture to restore him to his usual strength, the case rapidly recovered. It will be recollected that the first time the quinine was ordered, a cessation of pain and other unpleasant symptoms occurred. On making strict inquiry,

I found the relief then experienced arose from his putting the truss aside for two or three days, in consequence of a small pustule on the skin, where one of the pads pressed upon, which sufficiently accounted for the relief.

It is not, however, so easy to account for the symptoms characterizing this case—that is, why simple pressure should have caused a partial erection of the penis, or a hardening of the urethral canal, also partial (only affecting a small portion of it), and, I may add, the excruciating pain at the neck of the bladder and in the perineum. The gentleman is now well, and the erections perfect.

A case of this nature shows the necessity of being particular in inquiries into the history, lest some important point should be hid from the medical attendant, which, if known, might greatly enhance the chances of cure.

PHLEGMONOUS ERYSIPELAS FROM SLIGHT WOUND IN THE HAND.—AMPUTATION OF THE ARM.—SECONDARY HEMORRHAGE.

By CHARLES EDWARDS, Esq., M.R.C.S., &c., Christian Malford.

John Hannam, a hale old man, seventy years of age, whilst cleaning out an empty sugar cask, ran the point of a rusty nail into the palm of his hand; the wound was trifling, but was quickly followed by violent inflammation of the phlegmonoid erysipelatous kind. For the first fortnight he was attended by a neighbouring practitioner, who used only palliative treatment. At the end of this time he came under my care, with the hand, wrist, and lower third of the forearm enormously swollen; the skin was of a dark crimson colour, and there were evident signs of extensive disorganization of the cellular tissue. I made two free incisions, five inches long, on the back of the forearm and hand, and let out a large quantity of matter, mixed with blood; the hemorrhage from the engorged vessels was profuse, but was easily checked by pressure. The patient was much relieved by this treatment, and for a time went on well, excepting that I was twice sent for during the week following on account of rather free and sudden bleedings, but as ulceration had extended to the carpal bones, and suppuration continued profuse, the man became hectic, and I found it necessary to remove the limb, which I did on the 8th of May, by the circular operation, above the elbow. Two arteries required ligatures, the humeral and another of considerable size, both of which were partially ossified; the stump was dressed in the usual way, and the patient put to bed. At two o'clock A.M., nine hours after the operation, there was considerable oozing of blood, and, as the usual means were insufficient to check it, I was obliged to remove the dressings and open the stump; the hemorrhage ceased, however, on exposure to the air, and matters went on well for a week, excepting that there was little disposition to heal. On the eighth day I was sent for, and found the old man quite exhausted from the effects of sudden and profuse hemorrhage; the tourniquet had been applied by his son, whom I had instructed in its use; on loosening it, and washing away the coagula, the bleeding did not return, nor could I discover whence it had come; the ligatures were firm. Cold-water dressings were applied; the patient gradually rallied and went on well until the thirteenth day, when the ligature came away from the smaller vessel, and six hours after another alarming hemorrhage occurred, which again reduced him much; it was checked, however, and treated in the same way as before, and did not return till the twenty-first day; the stump in the meantime looking better. On the morning of this day the principal ligature came away; and in the evening, during a violent fit of coughing, the vessel gave way and bled profusely; the patient's son, who was in constant attendance, quickly arrested the hemorrhage by pressure on the arterial trunk; on my arrival this pressure was for a moment withdrawn, and a jet of arterial blood followed; I,

therefore, at once proposed to cut down to and secure the vessel; but the old man, who was very weak, and his friends, were so determined that the operation should not be performed, believing that he would die under it, that I was obliged, much against my will, to trust to pressure, and leave him for a time; it so happened, however, that during the night the tourniquet slipped, and in a moment the patient was deluged with blood. On my arrival he was in a state of extreme exhaustion, pulseless, and apparently dying; the bleeding had ceased; after readjusting the tourniquet, all our means were directed towards restoring animation; for twelve hours there was no disposition to rally, the patient lying in a state of lethargy, and only indicating by his breathing that he lived; from this time he rallied slightly, but for three days he had involuntary discharges from the bowels, and the bladder was only relieved by means of the catheter; the stump was assuming an unhealthy appearance, the matter discharged dark and offensive. The tourniquet, which had been applied with gentle pressure near the axilla, was now removed; there was no bleeding; lint, soaked in equal parts of lemon-juice and spirit of wine, was applied to the stump, and the patient allowed a generous diet. Under this treatment he gradually improved; the stump sloughed a little, and left a tolerably healthy granulating surface. There has been no bleeding from that time to the present (ten weeks from the operation); the stump is almost entirely healed; the man has had general anasarca, but is now nearly free from it, and is able to walk a mile without assistance. The arterial trunk seems to be completely obliterated from the point near the axilla, where pressure was made.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of July 19; M. BRONGNIART in the Chair.

SPARKLING SYNCHISIS.—M. Bouisson, professor of the University of Montpellier, offered, in a short communication, another explanation of the singular phenomena, to which we have already on various occasions referred, under the names of "sparkling synchisis." According to M. Bouisson, the vitreous humour of the eye contains a certain amount of fatty matter, which may, under the influence of accidental circumstances, be deposited in the shape of minute bright particles.

EFFECTS OF QUININE ON THE BLADDER.—M. Duchassaing, physician at the Guadeloupe, stated that he had in several instances noticed stranguity and hematuria consequent upon the exhibition of sulphate of quinine. The powder of the cinchona bark did not produce these effects; and M. Duchassaing was inclined to attribute its innocuity to the presence of tannic acid. It would be, therefore, sufficient, in his opinion, to add some acid substance to sulphate of quinine in order to prevent its injurious action on the urinary organs.

ACADEMY OF MEDICINE.

Meeting of July 20; M. BROWN in the Chair.

ELECTION OF A SECRETARY PERPETUEL.—The entire meeting was occupied by an uninteresting debate on the expediency of electing a successor to M. Pariset. It was decided, however, that the election would take place in one month.

The meeting adjourned at five o'clock.

TREATMENT OF HICCOUGH BY PRESSURE ON THE EPIGASTRIC REGION.—We mentioned, some weeks since, that, in one of his clinical lectures, M. Rostan had recommended this very simple method for the purpose of relieving obstinate hiccough. Dr. L. Boyer, in the last number of the "Medico-Chirurgical Review" (of Paris), relates three cases of painful and obstinate hic-

cough in which the symptoms were instantaneously dispelled by compression of the epigastrium with an appropriate bandage. Borden had already recommended this plan, which had fallen into oblivion, and which deserves to be made known for the double merit of its efficacy and of its simplicity.

CHORIONITIS.

Professor Forget, of Strasbourg, describes, under this name, a disease of the skin which seems hitherto to have escaped the attention of pathologists. In January, 1837, a woman, aged thirty-three, who had for several years suffered from articular rheumatism, was admitted into hospital. The wrists and ankles were in a state of partial ankylosis, due less to the disease of the joints than to a singular thickening and induration of the skin, which was hard, stretched, brownish, and closely resembled in appearance the nodular tissue of scars. The same alteration of the skin was noticed in most parts of the body; thus, from the tension of the integument the countenance had lost its expression and its mobility, the movements of the neck were interfered with, the skin of the abdomen was in the same condition; in one word, the envelope of the body seemed to have become too tight for the subjacent parts. Emaciation, doubtless, produced by the compression of the tissues by the diseased skin was present. The various functions were, however, performed with regularity, and the patient underwent, without any benefit whatever, several forms of treatment. A second case of the same sort was observed in February, 1847, by Dr. Grisolle, at the Hôpital Saint Antoine. The patient, a woman, aged fifty, had presented the first symptoms of the disorder at the period when she ceased to menstruate. The arms and face were chiefly affected, the skin of these regions being in a considerable state of tension; the sensibility, temperature, and colour of the integument were not modified. Some improvement was derived from the use of alkaline baths and the exhibition of hydriodate of potash.

Placing these two cases in juxtaposition, Professor Forget concludes that they belong to a hitherto undescribed form of cutaneous disease, to which he gives the name of chorionitis, or scléro-sténosis (from σκληρός—hard, and στενός—narrow).

SIGNS INDICATING THE PRESENCE OF WORMS. By Dr. HUBSCH.—The dilatation of the pupil, the itching of the nose; trismus, constipation, or diarrhoea; umbilical colic, derangement or depravation of the appetite, subsultus tendinum, &c., are the signs generally considered to indicate the presence of intestinal worms. M. Hubsch calls the attention of medical practitioners to three symptoms of another nature, and which he considers as very important. The first is the particular appearance of the tongue, which is generally covered with a white deposit interspersed with red specks, usually confluent at the edges or towards the apex of the tongue; the second is increased salivation; and the third, a special kind of chattering, produced during sleep by the spasmodic grinding of the teeth. The latter symptom is, according to Dr. Hubsch, present in nine cases out of ten.

THE INVENTORS OF ETHEREAL INHALATION.

Ethereal inhalations have now literally travelled round the world; but if surgeons do not altogether agree upon their mode of action—if their results are not equally appreciated by all—still most physicians are of one mind on the undoubted utility of the method in certain specified cases. It is, therefore, not uninteresting, at this stage of the history of the invention, to endeavour to ascertain to whom the credit of the discovery is really due, particularly as a considerable degree of discord appears to prevail in all places, particularly in America, on the subject.

Mr. Morton, Dr. Jackson, and Mr. Wells lay claim to the invention, and in the midst of contradictory statements it is no easy matter to wade towards the truth. In a somewhat lengthy pamphlet "On the Origin of the Lethæon," published in Boston by Mr. E. Warren, Dr. Jackson is accused (to use a popular but graphic

expression) of introducing his fingers into every body's pie. Dr. Jackson, however, on Mr. Morton's own admission, appears to have been repeatedly consulted on the substance to be employed, the apparatus, &c.; and his suggestions were sufficiently valuable to induce Mr. Morton to offer him a share in the profits to be derived from the invention. It appears equally certain that Mr. Morton, acting upon those suggestions, did successfully employ the ethereal inhalation, and was the first to publish the results and claim their reward. In the *Boston Medical and Surgical Journal* of June 18, 1845, we find, however, the following passage, in which the discovery, professed to have been afterwards made by Messrs. Jackson and Morton, is spoken of as a matter of sufficient notoriety to require only a cursory notice:—

"The nitrous oxide gas has been used in quite a number of cases by our dentists, during the extraction of teeth, and has been found by its excitement perfectly to destroy pain. The patients appear very merry during the operation, and no unpleasant effects follow."

In a subsequent affidavit, signed by Dr. Ellsworth, the author of the article, it is stated that the expression, "our dentists," applied to Dr. Wells, who to his full knowledge administered the nitrous oxide gas in 1844, and that many teeth were extracted without pain under its influence.

If, therefore, the merit of the discovery lies in the establishment of the principle that pain may be prevented during operation, by the inhalation of medicated vapours or gases, and not in the use of one particular substance, be it nitrous oxide or ether, it is clear that the credit of the invention and of its earliest application must be awarded to Dr. Wells, in preference to his two competitors. But how are we to couple Dr. Wells's pretensions with the fact of his having for so long a time kept to himself a discovery of this importance, and claimed it only after it had become successful in other hands? How are we to judge of them when we read in his letter to Dr. Morton, dated Oct. 20, 1846:—

"If the operation of administering the gas is not attended with too much trouble, and will produce the effect you state, it will undoubtedly be a fortune to you, provided it is rightly managed."

Must we not forcibly conclude either that Dr. Wells had completely given up his previous researches on the subject, finding the exhibition of the gas too troublesome to be practicable, or productive only of unsatisfactory results; otherwise, how could we understand his abandoning a system which (in his own words), if rightly managed, would be an undoubted source of fortune?

We think, however, we can set these various claims at rest by the following extract from the printed reports of the Academy of Medicine of Paris:—

"Meeting of September 23, 1828.—('Archives Générales,' vol. 18, first series, page 453).—*Painless Operations.*—M. Gérardin reported on a letter written to his Majesty Charles X., by Mr. Hickman, a London surgeon, in which that gentleman asserted he had discovered the means of performing the most troublesome and dangerous operations without pain. The method consisted in producing temporary insensibility by the methodical introduction of certain gases in the lungs. Mr. Hickman had made numerous experiments on animals, and was desirous of obtaining the co-operation of the leading physicians and surgeons of Paris, in order to make the same experiments on the human subject."

This passage is sufficiently explicit; no doubt can be entertained; the principle was discovered by Mr. Hickman, and it is in the principle that the invention resides. Mr. Hickman took, in our opinion, the safest and best measures for the carrying out of his invention: they failed, but not by his fault. A scientific body was, by him, put in possession of the facts; the communication was made generously and freely; no

pecuniary profits to himself; it was the gift of a man of science to the world. In all probability Mr. Hickman is no more, or he would, doubtless, have arisen to defend what we must, in justice, consider as his property—the discovery of the method of performing operations by the inhalations of medicated vapours.

CHEMICAL COMPOSITION OF THE BLOOD.—M. Poggiale, surgeon of the Military Hospital at Lille, forwarded to the Academy of Sciences, at its last meeting, some researches on the composition of the blood in man, and in domestic animals. The results of his investigations do not differ from those of M. Lecanu, as far as the human blood is concerned; with regard to animals, the following are the chief conclusions of M. Poggiale analytical inquiry:—The blood of birds contains a larger proportion of globules than that of mammifera; and in carnivorous animals globulin is more abundant than in herbivorous tribes. In the latter, albumen is found in greater quantities than in the blood of carnivorous animals or of birds. Fatty matter constitutes 2-1000 of the mass of blood of animals. Human blood is the least watery of all; birds present less water in their circulating fluid than other animals. The soluble and insoluble elements of the blood vary between 8.45 and 11.84 for 1000 parts.

D. MC CARTHY, D.M.P.

Diet in Infancy. Dr. Klencke calls attention to the important deterioration which the milk of stall-fed cows undergoes, and is inclined to attribute the production of scrofula in children in many instances to its direct transmission, through the medium of that fluid. "Although the direct production of scrofula," says Dr. West, "by the contagious properties of the milk is assumed rather than proved in this pamphlet, still the fact is very important, that stall fed cows often become tuberculous, and that their milk loses much, or even the whole, of its sugar; that the butter and casein diminish, while the albumen is found sometimes in as high a proportion as 15 per cent., and claim in the proportion of 1.4 per cent.; and that in some cases lactic acid is likewise present." Dr. Marotte draws attention to the error often committed in placing infants on a spare diet, who have been observed not to thrive at the breast, but to suffer from diarrhoea. The real means of cure would consist in obtaining a wetnurse, and thus providing the child with more instead of less nutritious food. Many instances of gastro-intestinal disorder in childhood depend on the want of a more highly assimilated diet. It is, therefore, as a general rule, undesirable to dilute the milk of the herbivora, already poor in animal constituents; while, in those cases where it is necessary to supply deficiency in the nutritive qualities of the nurse's milk, chicken or other broth, either alone or mixed with milk, should be used for that purpose.

Singular Termination of a Case of Uterine Polypus.—It occurred in the practice of Dr. James Johnson, of the State of New York. The patient was a married lady and had been afflicted for twelve months with the symptoms usually consequent upon the occupation of the womb by a tumour. This had existed during the period, and was found to be attached to the cervix uteri. It having been decided to remove the morbid growth, the medical gentlemen proceeded to the house for that purpose, when they found that the polypus had entirely detached itself a day or two previous, just at the period she looked for her regular menstrual discharge, which had never been interfered with until the two preceding menstrual times. The tumour had the appearance of bloody coagulum, and melted away, as it were, under the touch.

Blindness caused by the Use of Sulphate of Quinine.—Dr. McLean, professor of materia medica in Rush Medical College, U.S., relates four cases in which blindness seems to have been produced by large doses of the quinine. In the first case, sixteen grains were exhibited every hour, in a case of low remittent fever. Before the quinine was discontinued the patient became perfectly blind, which was slowly and

gradually removed during the first year. In the second case, the quinine was also prescribed in large doses, producing blindness, which, however, was removed in a few weeks. In the third case the quinine was prescribed in three-grain doses every hour, and continued for three days. The blindness took place on the third day. After some weeks the sight became partially restored. In the fourth case, three drachms of quinine were taken in thirty-six hours, in doses of six grains, and at the end of that time the patient became perfectly blind. On the two succeeding days his sight, although very imperfect, was considerably restored.

Rheumatism, with Hypertrophy of both Eyes.—The patient was a negress, fifteen years of age, under the care of Dr. William M'Pheeters U. S. She was first attacked with intermittent fever, which continued for some months, accompanied with a severe pain in and over each eye. The pain continued from the fall of the year till the approach of fine weather, when it gradually ceased. The eyes exhibited no unhealthy appearance either in size or colour. In the following winter the pain returned with increased severity, occasionally throwing her into convulsions. From the commencement of this pain, the eyeballs began to enlarge and protrude, increasing as the pain continued, until they became so large as to create alarm lest they should burst. When the distention was very great, an emetic of ipecacuanha was prescribed every morning for ten or fifteen days, without any material improvement; indeed the effort of vomiting rather increased the swelling of the eyes. By the middle of March, the pain was very severe, continuing day and night; the eyes immensely protruded, standing out an inch beyond their ordinary level, and presenting a hideous appearance; left eye larger than the right; a constant and copious flow of tears from both eyes; light very painful, and sight imperfect. The eyelids could not reach entirely over the balls. No appetite; skin dry and husky; emaciation great; tongue covered with a thick, dark-coloured coat. The patient was ordered to take five grains of the hydriodate of potash three times a day; to paint the eyelids daily with tincture of iodine; to keep a cloth wet with mucilage constantly over the eyes; chronic blisters to the back of the neck, occasional aperients; and a mild nutritious diet. Under this treatment the patient rapidly improved. At the beginning of May the pain had almost gone, the eyes were very much reduced in size, and her general condition improved. By the middle of the month she was free from pain; eyes the natural size, sight perfect, and was enabled to resume her ordinary duties as house-servant.

Cyanosis.—A young man, twenty years of age, by trade a baker, was admitted into the Cincinnati Hospital, under the care of Dr. J. P. Harrison. The patient said he had been subject for the last five years to some degree of blueness of the general surface of the body. When admitted into the hospital there was difficult respiration; much lividity over many parts of the surface, especially the ears, the lips, and the fingers; great protuberance of the eyeballs; slight oedema of the eyelids; tongue very hard; the external jugular, and smaller veins of the neck, much enlarged and varicose; pulse irregular and indistinct; and general temperature of the body, especially on the extremities, low. A slight movement of the patient caused increased lividity of the countenance. The bowels were regular. The patient lived but three days after admission, the blueness augmenting till his death. The autopsy showed the heart much enlarged in size; the right ventricle was hypertrophied to a great extent, and its cavity much dilated. The right auricle was expanded into a bag sufficient to contain half a pint of fluid. The foramen ovale was imperfectly closed, there being several openings through it, large enough each of them to admit a small quill. The tricuspid valve did not close up the auricular ventricular space. The right lung was healthy. The left lung exhibited a singular appearance; partial emphysema was

obvious in different portions of the interlobular tissue, but in a most remarkable degree these were exhibited three large collections of air, each of the size of the urinary bladder when containing about a pint of fluid. These collections were obviously produced by the air escaping from the cells of the pulmonary structure, and collecting within the pleura pulmonalis.

Removal of the Superior Maxilla for a Tumour of the Antrum.—Return of the Disease.—The patient was a negro, aged eighteen. The disease first manifested itself as an excrescence from the gum, which was several times removed and cauterized, being always reproduced soon after. In the course of five or six months the cheek began to bulge out. Early in January, Dr. Sims, of Montgomery, United States, saw him. The tumour had then become as large as a good-sized orange, occupying the entire extent of the left upper jaw, and involving to some degree the molar bone. The mouth was in a bad condition; the gums purple, tumid, and bleeding on the slightest touch; teeth decayed, while at other points they were firmly ankylosed with their alveoli. The operation was performed after the teeth had been extracted, the gums scarified, and his general health improved. The cheek was opened by the curvilinear incision, according to the process of Warren and Velpeau, taking particular pains to avoid the parotid duct. The facial artery being secured, the anterior flap was dissected up to the edge of the orbit. The alar nasi and frenum of the lip were cut up to admit the more easy elevation of the flap. The origin of the inferior oblique was divided, and the contents of the socket separated from the orbital plates of the maxillary and molar bones. The zygomatic face of the maxilla was freed by a downward dissection of the lower flap. It now remained to attack the hard parts. The left lateral incisor being extracted, an incision was made through the mucous membrane near to and parallel with the longitudinal palatine suture. Two or three nips of Liston's bone-forceps easily divided the alveolar and palatine processes. The eye and its appendages were then supported by the handle of a light silver spoon bent at right angles, while the nasal process was divided obliquely downwards, so as to avoid injuring the nasal duct. The broad part of the molar bone was next divided into the spheno-maxillary fissure, which was more easy than the section of the nasal process, simply because it was more accessible. The separation of the palate plate from the palate process of the maxilla was effected by a thrust with a strong-pointed bone-knife. The other bony attachment, with the pterygoid process of the phenoid bone, was separated by another thrust with the knife laterally. The diseased mass, being now movable, was slanted slightly downwards, and the operation was quickly completed by clipping the remaining attachments with the scissors. Not a vestige of the disease was left behind. No ligature was applied except to the facial artery, and that was removed before the wound was dressed. The wound was closed by interrupted suture and adhesive plaster. There was no stuffing of the cavity, and no other dressing. The recovery was rapid. The tumour was perfectly round, osseous, and scirrhous. The central portions of it were filled with stellations of bony matter, sending off spangled radiations towards the circumference of the scirrhous mass. The disease returned in the short space of two months, a tumour forming larger than the other, which was again removed. It was discovered, after another operation, that it was useless, the disease again returning, and in a few months he died.

Structure and Formation of the Nails of the Fingers and Toes.—Mr. Rainey, in a paper read before the Microscopical Society, stated that the nail consists of at least two distinct structures: one proper to it—the horny structure; and the other the same as the cuticle: and also that the matrix of the nail possesses a set of vessels expressly for the purpose of secreting the horny matter. The matrix consisting in that part

which corresponds with the lunula, or semicircular whitish portion of the nail; of several rows of convoluted and variously-twisted capillaries, their direction being from above to below, which vessels appear to be for the secretion of the horny part of the nail, and may, therefore, be termed the horn-vessels. Other vessels are employed to secrete the cuticular matter of the nail. Between these is situated a plexus of vessels, whose office appears to be the secretion of a substance intermediate in its properties between horn and cuticle, and serving to connect these together, and thus to facilitate the protrusion of the horny part of the nail, properly so called, and to preserve its connection with the surrounding integuments.

Spontaneous Cure of Aneurism of the Arch of the Aorta.—Dr. Bellingham relates, in "The Dublin Medical Press," the case of a woman, sixty-four years of age, whom he attended, in St. Vincent's Hospital, in consequence of gangrene of the right lower extremity, which had commenced six weeks previously upon the anterior surface of the tibia, and had extended gradually till the muscles of the leg were laid bare, and the gangrene had reached to within a few inches of the knee, before she died. Her chest being examined while in hospital, nothing unusual was observed, except a double sound similar to that of the heart, which was audible below the right clavicle, as if the sounds of that organ were transmitted beyond the usual limits. The heart action was perfectly regular and natural. On a post-mortem examination, an aneurism of the aorta was found, which sprung from that part of the arch where the ascending joins the transverse portion, and extended across the sternum to the right clavicle, where it formed adhesions to the right lung. It was about the size of the closed hand of the subject, and was completely filled with concentric layers of fibrine, which was very firm, and evidently of some standing. The aorta was dilated, its inner coats much distended with numerous ossific patches, and the orifice, by which the aneurismal sac had communicated with the aorta, would admit the point of the finger. The heart itself was about the normal size; the left ventricle was hypertrophied, its cavity diminished in size, and the left auriculo-ventricular orifice was smaller than natural; the right auriculo-ventricular orifice was normal; the valves were healthy; both coronary arteries were ossified; the femoral and popliteal arteries of the affected side were diseased, and the popliteal vein contained a firm conglomeration.

Fatal Hemorrhage from the Umbilical Cord three days after Birth.—Dr. Keiller stated to the Edinburgh Obstetrical Society that he had been called to examine a case of fatal umbilical hemorrhage. It occurred in a fine plump male child, which was affected with vomiting from time to time. On the third day it was discovered that the binder, &c., of the child were soaked with blood from the navel. The cord was not examined for two or three days afterwards, when it was found that the bleeding point was at the root of the cord, to which was applied nitrate of silver, which seemed at the time to be sufficient to prevent the further continuance of the hemorrhage. Before half an hour had elapsed, however, the medical attendant was again summoned, when he tied a ligature around the umbilicus, embracing a portion of the skin which formed its circumference. The treatment proved too late, for the child died in a few minutes after the application of the ligature.

Fungating Excrescences of the Umbilicus in Infants.—Dr. Simpson stated that in infant, after the cord had dropped off, instead of the raw surface contracting and healing, he had several times seen large granulations appear, and raised, elevated, fungus-like excrescence form at the umbilicus. These generally shrink after a time, on being touched with alum or nitrate of silver. In one case he had lately seen, this simple treatment had little or no effect. The excrescence enlarged to the size of a cherry, which it likewise resembled in colour. It was apparently insensible to the touch, but blood oozed from its red surface under

slight handling. After several weeks a ligature was passed round its base, and in a few days it dropped off.

Treatment of Inflammatory Induration of the Cervix Uteri by deep Cauterization with Potassa Fusa.—Dr. Simpson states, in "The Monthly Journal of Medical Science," that he agrees with others in regarding the general dependence of leucorrhœa upon inflammatory ulceration and induration of the cervix uteri. The cure by the application of leeches, counter-irritation to the sacrum, &c., is tedious. Various local escharotics—partly to destroy the indurated tissues by direct decomposition, and partly to soften down the remainder by new inflammatory action—had been in modern times employed for the same purpose, and with much more certain and expeditious effect. Dr. Simpson has found the common *potassa fusa* far more manageable, speedy, and certain, than any other method. He used it through the speculum, applying a stick of it freely with a proper caustic holder to the ulcerated and indurated tissues. It required to be rubbed, or held strongly for a time, against the part which was to be destroyed. In general a piece, three quarters of an inch or an inch long, was melted down. The decomposition produced by it often caused a hissing sound. If the induration is extensive, and the whole cannot be removed at once, increased action and absorption are set up in what remains, and the parts adjacent become softened and diminished in size. Absorption in this way was truly one of the results of inflammation, though still an undescribed termination. In some aggravated cases, two or more applications of the caustic are required, at intervals of eight or ten days. Pelvic cellulitis, or any other bad result, has never been seen to follow. The appearance after the operation is as if a portion had been clean cut out with a knife. A large quantity of vinegar and water is immediately thrown up through the speculum to neutralize the potassa and prevent it from injuring the sound parts. A copious purulent discharge usually follows for several days, requiring the use of astringent washes, or zinc ointment per-aries. When the whole of the induration is once removed, the remaining ulcer heals rapidly and permanently. An ulcer over a diseased part may be cicatrized, but it is almost sure to break out repeatedly till the induration is reduced.

Sclerosis of the Cellular Tissue in Newborn Children.—Dr. Eman Mildner, of Prague, observes that the disease attacking many children who have been treated, when in a state of asphyxia, successively by tepid and cold effusions; its greater frequency during cold or humid cold seasons; its sudden occurrence in many newborn infants, who, after warm bathing, were exposed incautiously to cold; and its presence in children born in the street, and during the first days of life, are facts which indicate the great influence of a change in temperature in producing this disease. In the treatment great care must be taken to prevent the disease, by avoiding as far as possible exposure of the child to any change of temperature. In foot and anus presentations, the parts which first appear should be carefully covered with warm clothes. The employment of cold affusion after tepid baths, for the revival of asphyxiated children, should be restricted to very rare cases. In the first degree, the most successful treatment consists of warm, dry, and aromatic fomentations; friction with flannel sprinkled over with camphor; tepid baths, and diaphoretics. In the second degree treatment is seldom beneficial; cold affusion is suggested at first, and then, having dried the parts, to cover them flannel, and to employ the same means as in the first degree. Post-mortem examinations yield satisfactory proof that morbid alterations of deep-seated organs are not connected with the origin of sclerosis, as there are many cases in which no changes but those in the skin can be discovered; that, when such alterations have been found, they, in most cases, are in no way related to the integumentary disease; that their presence, notwithstanding, considerably influences the progress of the case.

Anatomical Lesions discovered in Acute and Chronic Rheumatism.—Professor K. E. Hasse, of Zurich, has made a close investigation into the morbid alterations of rheumatic parts, and obtained the following results:—The cartilages of the affected joints were found of a reddish hue. The surface of the articular bony extremities presented scattered red spots of different sizes, and intensity of colour, extending from 2 to 6" deep into the spongy osseous substance. The foramina of the bony substance were all filled to about the same depth with dirty-red, soft, and friable pulp, very different from their normal fatty contents. A microscopic examination of this matter was found to consist of aggregated cells of nearly similar size (0.0046 to 0.0056), with turbid contents, and of a globular form, although some appeared to be flattened. Treated with acetic acid, these cells exhibited either a tolerably large nucleus or two or three smaller ones, each of which contained a nucleolus. These could be observed in some of the cells without adding acetic acid. There were, also, numerous blood corpuscles, and, in some places, many capillaries, varying in shape, having sinuous walls and a winding course. There were only a few flat fat cells present, several of which had a particular shape. The whole cell-wall, or a considerable portion of it, was separated from the usually homogeneous contents, and the free interval thus formed was more or less filled with oily granules. Occasionally a little spot of bright yellow was seen among the dirty-red colour, and in these places the cancelli contained fat cells and blood corpuscles. The reddened portions were dotted with lenticular spots of a pale yellowish colour, which were sharply circumscribed. At these points the osseous texture was diminished to a few fragments, and the foramina were filled with a soft yellowish pulpy substance, consisting only of aggregated elementary granules, such as is seen in chronic inspissated abscesses, and in the remains of decayed tubercular matter. In each case the adjacent non-reddened bony substance contained only fat cells, amongst which were seen, here and there, ruptured capillary vessels; but in no instance the before-mentioned poly-nucleated cells. In many cases the cartilage covering the bone was irregularly attenuated, the attenuation being most considerable at the margin of the joint, and, although apparently dissolved or rubbed off, it retained its smooth surface. Sometimes the bone was deprived of its cartilaginous covering, and perpendicular or flat foramina were exposed, varying from 2 to 4" in diameter, and from 2 to 8" in depth. It is thus rendered certain that in rheumatism the cellular tissue, as well as the bony substance, may become the seat of inflammatory exudation. It is even probable that in the great majority of cases, especially the slighter ones, their true morbid anatomy, which was formerly unknown, consists in the alterations of these tissues now described.

Psoitis.—Inflammation of the sheath of the psoas muscle is distinguished from inflammation of the cellular tissue in the internal iliac fossa, by the involuntary flexion, in the former, of the thigh upon the abdomen. Sometimes the two diseases coexist. The first is, perhaps, the less frequent but the more serious affection.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

J. M. ARNOTT, Esq., F.R.S., President.

FATAL CASE OF DYSPHAGIA, PRODUCED BY A POLYPOUS GROWTH IN THE ESOPHAGUS.

By R. ARROWSMITH, M.D.,
Senior Physician to the Coventry and Warwickshire Hospital.

(Communicated by Richard Partridge, Esq., F.R.S., &c.)

The patient, a ribbon-weaver, aged forty-eight, not previously unhealthy, came under the author's observation at the hospital, in March last, having much difficulty of swallowing, with

frequent and, at times, severe cough (always excited by attempts to swallow, but occurring independently of them); copious frothy expectoration; fever, but no dyspnoea. The dysphagia gradually increased until deglutition became nearly impossible. Attempts were made to pass a tube into the œsophagus, but without success, and they occasioned at the time so much spasm of the glottis as to endanger life. It occurred to the author that, if tracheotomy were performed, respiration might be carried on through a tube left in the trachea, while more persevering attempts were made to pass instruments into the œsophagus. This operation was therefore performed, and a tube left in the trachea. After this the attempts to pass a tube proved equally unavailing, though the power of swallowing was improved for a few days. The dysphagia, however, shortly increased, and death ensued on the 14th of May, purely from inanition, about fourteen weeks from the apparent commencement of the disease. On examination after death, a polypous growth was discovered at the commencement of the œsophagus immediately behind the glottis; it was rather larger than a walnut, and attached by a short fibrous base, commencing about half an inch from the posterior commissure of the glottis, and extending for the same distance in a straight line in the axis of the œsophagus. The tumour formed, on the one hand, a mechanical obstacle to the perviousness of the œsophagus, and on the other, by passing under the epiglottis during attempts to swallow, prevented the closure of the glottis, and thus allowed fluids to pass down the trachea. The author, in conclusion, refers to various writers who have related cases of polypus in the œsophagus, but remarks that the one now recorded differs from any he has seen referred to, in the dysphagia being complicated with, and greatly increased by, the tendency of food to pass into the glottis.

A CASE IN WHICH A LARGE POUCH WAS FORMED IN THE ŒSOPHAGUS, IN CONNECTION WITH CONTRACTION OF THE CANAL.

By W. C. Worthington, Esq., F.R.C.S.,
Senior Surgeon to the Lowestoffe Infirmary,
&c.

The author commences by observing that this lesion has been noticed by Sandifort, Meckel, Copland, and Rokitsky, and refers more particularly to two cases described by Mr. Ludlow, of Bristol, and Sir Charles Bell. The case now related was that of a gentleman, aged sixty-nine, of robust constitution, who experienced slight dysphagia for three years before his death. In January, 1846, deglutition became more impeded, accompanied with emaciation. In July the author was consulted, when there was great difficulty in swallowing, especially solids, and the passage of any food by the œsophagus was attended with a gulping noise. After consultation with Mr. Crosse, of Norwich, attempts were made to pass bougies, but they proved abortive. From this time the patient gradually lost flesh, though he continued to take food, and it was often observed that a portion appeared to be swallowed, and for a time retained, but was shortly returned by regurgitation, little changed. For some weeks before death the patient was sustained solely by nutritious enemata. On examination after death a pouch was found behind the œsophagus, opposite the cricoid cartilage, hanging down between the trachea and œsophagus, three inches and a half long, and two inches and a half in circumference. Immediately behind the cricoid cartilage, and on a level with the commencement of the pouch, there existed a stricture formed by a transverse fold of mucous membrane, admitting only a large-sized urethral bougie; the œsophagus below was contracted, but the mucous surface healthy. The author concludes with some remarks on the diagnosis of these cases during life, and the best mode of treating them.

Dr. Coley stated, that he had met with a case somewhat analogous to the first case—to that detailed by Mr. Worthington. The patient was

a medical man, who suffered from the symptoms of dysphagia for sixteen years. He consulted the late Mr. Cline, by whom the existence of a preternatural pouch in the œsophagus was discovered, but who overlooked the principal cause of disease—a stricture of the upper part of the œsophagus. The patient was under Dr. Coley's care only during the last three months of his life. Whalebone bougies, of a peculiar construction, similar in form to those used by Sir Charles Bell, were employed, but appeared to produce considerable irritation. The patient died from inanition and excessive thirst, he being totally unable to swallow liquids even. There was one symptom which was present in this case, which has not been mentioned by writers—excessive congestion of the velum pendulum palati, the tonsils, and, indeed, of the whole throat. At the post-mortem examination, there were found a pouch of three inches long, and one in diameter, at the lower part of the pharynx, and a stricture at the upper part of the œsophagus, in an advanced state of carcinoma. The stricture, Dr. Coley thought, was the primary disease; the pouch of ulterior formation, the result of a process similar to that which takes place in the bladder, by the separation of its fibres, from severe and long-existing stricture in the urethra. A case of stricture of the œsophagus was published in one of the medical journals many years since, which was cured by mercury; and he (Dr. Coley) believed that a similar result would follow the exhibition of mercury and iodine, in the treatment of incipient stricture of the œsophagus, providing it were not dependent on carcinoma. He thought there was some analogy between these cases and the stricture in the lower part of the intestinal canal. Dessault published the particulars of stricture in the lower bowel, cured by the internal use of mercury. The disease was supposed to be of syphilitic origin, but of that there was not any positive proof. He (Dr. Coley) had, at that time under his care a case of stricture of the rectum, with copious offensive discharge, which was getting well under the use of mercury; and in that instance the disease was decidedly not syphilitic. He thought this plan of treatment should be had recourse to in all cases, before employing local remedies, the use of which he deprecated, as likely to cause great suffering and irritation, such as marked their application in the case he (Dr. Coley) had detailed.

Mr. Arnott remarked that the late Dr. Cline had the reputation of being one of the ablest surgeons this country had ever produced. Dr. Coley had stated that Mr. Cline had detected the existence of the pouch in the œsophagus, but not that of the stricture. He (Mr. Arnott) wished to know how long a time elapsed between Mr. Cline's attendance on the case, and that of Dr. Coley, and also how Mr. Cline had ascertained the existence of the œsophageal pouch?

Dr. Coley replied, that the patient was seen by Mr. Cline about sixteen years before his death—before the more distressing symptoms of stricture had occurred. The only symptoms of the disease were, regurgitation of fluids, and difficulty of swallowing. The existence of the pouch was recognised by the bougie.

ON THE STATE OF THE NERVOUS SYSTEM IN PARALYZED LIMBS.

By R. B. Todd, M.D.

In this paper Dr. Todd demurs to the views of Dr. M. Hall, which ascribe an increased irritability to the muscles of paralyzed limbs, where the lesion is in the brain, and make a distinction between spinal and central palsy in the loss of irritability in the paralyzed muscles in the former case, and its augmentation in the latter. Dr. Todd adduces a series of trials, on cases of hemiplegic paralysis, by means of galvanism, in the great majority of which the palsied muscles respond less to the galvanic stimulus than the healthy muscles; while in others, again, they are equally excitable with the muscles of the sound limb. The author adduces proofs to show that the difference in the excitability of the

muscles, in cases of paralysis, is due to the different state of the nervous force in the nerves of the palsied limbs: in one class of cases it is in a minus condition; in the other it is in a plus condition, and in a third it is unaffected by the cerebral lesion. The author further points out that, in truth, the muscular irritability has nothing to do with the phenomena in question; that that power is always in direct proportion to the nutritive condition of the muscles; and that the effects of galvanism, when propagated through the nerves, is not a true test of the state of the irritability of the muscles, but rather of the excitability of the nerves themselves. Dr. Todd offers a new explanation of the tendency of strychnine to affect paralyzed limbs first. According to this view, the strychnine accumulating in the blood is attracted in greatest quantity to the side of the brain on which the lesion exists, and excites irritation there, which, according to the usual law of cerebral influence, is propagated to the opposite side of the body, or to the paralyzed muscles.

CASE OF POPLITEAL ANEURISM.

By W. H. Judd, F.R.C.S.E.,
Surgeon in Ordinary to his Royal Highness
Prince Albert, Surgeon-Major Scots Fusilier
Guards, &c.

(Communicated by Dr. Webster.)

Corporal D., aged thirty-two, was an agricultural labourer in 1827, when he suffered from a severe fracture of the right thigh, and the bone was again broken before the cure was complete. He came under the author's care in October, 1846, for a pulsating tumour, about the size of an egg, in the right popliteal space. This could be emptied, and the pulsation in it was arrested by pressure on the femoral artery; in short, it was clearly an aneurism. His health was good. He was bled twice to sixteen ounces, and purged; but, the symptoms remaining unrelieved, it was decided to try the effect of pressure, with which view the Italian clamp was employed. This was worn irregularly, in consequence of the patient not being very tractable, for four days; and on the fifth, although forbidden to rise from the horizontal posture, he removed the clamp, and got up, and soon felt something give way, and a hot sensation extending down his calf. This was followed by swelling and pain in the leg, together with faintness and pallor. After a consultation with Messrs. Keate and Guthrie, the author determined on placing a ligature round the femoral artery in the usual position. The operation was forthwith performed (Nov. 1st), and followed by relief to the patient's suffering. On the third day, the wound was nearly healed, except where the ligature hung out; but the pulse was very rapid, and the temperature of the limb low. The calf also was blue, and the foot œdematous. On the fourth day, a blush appeared in the ham, and gangrene speedily supervened. On the eighth day, an incision was made through the slough into the aneurism, and putrid serum flowed out. Tonic treatment and support were continued. On the twelfth day, symptoms of trismus made their appearance; and on the fourteenth, the tetanic spasm had extended to the frame generally, when death put an end to his sufferings. On examination of the limb, the false aneurism was found to occupy the whole calf, and was lined by a dark-red and inflamed membrane. The femoral artery was plugged above and below the ligature. The popliteal artery entered the upper part of the true aneurism, and projected about two lines within the sac, above and below, where it appeared like a tube broken irregularly across. The author concludes by some observations on the cause of mortification and tetanus in this case, and by expressing his opinion that the injury received in 1827 may have laid the foundation of the disease which ultimately proved fatal to his patient.

ON A PECULIAR INJURY OF THE UPPER END OF THE HUMERUS, ENTERING INTO THE COMPOSITION OF THE SHOULDER-JOINT, OBSERVED IN SIX

CASES; WITH A DESCRIPTION OF THE APPEARANCES DISCOVERED SOME YEARS AFTERWARDS, ON THE DEATH OF ONE OF THE SUFFERERS.

By G. J. Guthrie.

(Communicated by the President.)

The author commences by drawing attention to a clinical lecture delivered by him at Westminster Hospital, in 1833, and subsequently published; and to a second, which he delivered in 1837; wherein he made some remarks on cases of an undescribed injury of the shoulder-joint. An opportunity having recently occurred, of verifying the diagnosis by examination after death, in the sixth case, he takes the opportunity of bringing the subject before the public, in consequence of the interest which naturally attaches to such cases, but especially because Mr. Smith, of Dublin, has expressed his belief that the injury in question was similar to one he had the opportunity of examining. After giving the report of Mr. Smith's case, from which it appears that "the greater tuberosity, together with a very small portion of the outer part of the head of the bone, had been completely separated from the shaft of the humerus," the author proceeds to describe the particulars of the sixth case. The subject of it was forty years of age, and his recovery was tedious; he, however, regained sufficient use of the arm for all useful purposes of his trade, except when he attempted to work above his head. In November last the man died, and the humerus was removed for examination. The opinion expressed respecting the nature of the injury, when under treatment, was, that there was a longitudinal split of the humerus, by which the small tuberosity was separated from the head of the bone, the anatomic neck of which was broken. This diagnosis proved essentially correct; but, in addition to the above injury, a second split appeared to have extended downwards, partly separating the greater tuberosity, and extending underneath, towards the shaft of the bone. The bicipital tendon was probably torn through at the time of the accident, as the groove was partially blocked by new ossific deposit. The author concludes by referring to some clinical remarks, bearing on the point, by Mr. Hancek, and by repeating his persuasion that Mr. Smith was mistaken in supposing that his (the author's) cases were similar to those which he (Mr. Smith) had described.

AN ACCOUNT OF THE STRUCTURE OF A SLAVE.

By John Birkett, F.R.C.S.

Demonstrator of Anatomy at Guy's Hospital.

(Communicated by T. B. Curling, Esq.)

The structure described by the author was a soft, bluish nevus, which was removed from the back of the hand of a young man, and consisted of areolar tissue, epithelium, with capillary and larger vessels. The mass was divisible into lobes, each possessing a distinct fibrous capsule. These lobes admitted of inflation, when isolated and encircled with a ligature; a subsequent section exhibited a reticular arrangement in their interior. The cells thus formed communicate with each other; but many of the lobes are isolated and distinct. The septa are composed of delicate fibrous tissue, covered by a tessellated epithelium; a basement membrane and yellow fibrous element are also present at various parts. The vessels (which were not injected) could not be traced into the septa, nor did they appear to open into the cells. Vessels, however, were discovered, passing from the corium to the septa upon which they were lost. Interspaces, or reservoirs, between the corium and lobes (communicating with each) have veins opening into them, and each lobe appears to possess two or three small arteries, which constitute its independent supply. The author remarks that these tumours are not exclusively entitled to the appellation of "vascular or bloodvessel tumour," and he regards them as more closely resembling the corpora cavernosa than any other tissue, and considers that they ought to be classed with the fibrous tissues, resembling them probably in their development and mode of nutrition. The author concludes with some practical remarks and an enumeration of the different modes of

treatment which should be adopted for the cure of the disease.

ON THE SOURCE OF HEMORRHAGE IN PARTIAL SEPARATION OF THE PLACENTA.

By W. D. Chowne, M.D.

The paper defended the doctrine, that in such cases the hemorrhage is essentially and mainly in the veins of the uterus, which become excited at that part whence the placenta is separated. Several inferences are adduced from the influence of contraction and non-contraction of the uterus—from the relative effects of hemorrhage on the mother and on the fœtus—from the character of the blood effused, and from analogical considerations in relation to the pulmonary circulation in extra-uterine life, and the placental circulation *in utero*. The paper adduces also inferences drawn from the anatomical structures, and the functions of the parts concerned; and, also, from the hemorrhagic phenomena connected with *inversio uteri*, together with the diagnosis founded on these phenomena; and it cites, with regard to the source of hemorrhage, as demonstrated to the observation, the experience afforded by Caesarean operations.

REVIEWS.

Report on the Climate and Principal Diseases of the African Station. Compiled from Documents in the Office of the Director-General of the Medical Department, and from other Sources, in Compliance with the Directions of the Right Honourable the Lords Commissioners of the Admiralty, under the immediate Direction of Sir Wm. Burnett, M.D., K.C.H., F.R.S. By ALEXANDER BRYSON, M.D., Surgeon R.N. London: 1847. Pp. 260. We have recently advocated the claims of the members of our profession serving in the army and navy to the respectful attention and honourable rewards of the Government, because of the valuable advantages which they confer, not only upon particular services, but upon every class of society. No body of men has exhibited greater zeal in promoting the welfare of our country, and none has manifested greater intelligence and devotion in endeavouring to trace up to their sources, and there to arrest, whatever is incompatible with the health and prosperity of mankind. We appeal to the work now before us as one of the proofs of the truth of our assertions: he facts which it states, and the manner in which they are discussed, entitle the author to great praise from the Government, the profession, and the people.

Dr. Bryson informs us, in his "Preliminary Observations," that his pages were compiled in consequence of a minute from the Lords Commissioners of the Admiralty, addressed to Sir Wm. Burnett, the Director-General of the Medical Department of the Navy, requesting him to cause to be embodied in a report such portions of the medical returns from the African station as might be deemed valuable. It required no small amount of labour and patience to examine documents which had been accumulating for twenty-seven years; and great discretion and tact to extract, condense, and arrange, whatever either of information or interest they might contain. In addition to this, his own personal experience on the station was to be used, that the greatest amount of information might be afforded "regarding the diseases contracted there; the localities most injurious to health; the precautions which might be taken to avert or diminish fever; and the mode of treatment regarded most effectual; embracing also the diseases most prevalent amongst the captured slaves." It may be considered that such a work can only be useful to those who, as medical officers in the Government or merchant service, are called to visit those shores where pestilence and death seem to have especially established their dominion. To medical officers on the station, as well as those who are called on occasionally to visit it, the work will be

especially useful—enabling them to study more conveniently the nature of the fevers peculiar to the climate, and at the same time enable them to deduce for themselves such plans of treatment as they may consider most likely to be successful. Such a work is not only useful to them, but to every member of the profession: here he may learn how theories the most plausible are oftentimes built on baseless fabrics, and that the treatment of disease according to certain fixed and established rules will never do at all times and under all circumstances. Of the African coast, where the slave trade is principally carried on, it has been remarked that it is "the grave of Europeans"—its jungles, its marshes, its climate, combining to impregnate every breeze with the invisible but energetic principles of disease and death. Scarcely has there been a vessel detained for any length of time on the station, whose crew has not been greatly weakened by the pestilential fever, while all the efforts of medical skill have appeared perfect weakness in coping with the disease.

The Topographical Remarks on the African Station, extending from Cape Verde on the North, to Cape Negro on the South of the Equator, which is the opening chapter of the book, is replete with interest. It is the key to the work, as we have here mentioned the different localities frequented by the cruisers when at sea; the various ports and harbours to which they resort in order to obtain provisions, wood, and water, or for refitting; and also the various slave establishments. Throughout the whole extent of the coast, it is more or less unhealthy; while the arduous duty of the man serves as a powerful predisposing cause for their being attacked with the fever. We are told that the duties performed by the squadron at the present day are executed in the same manner as nearly as possible, with an equal degree of diligence, as during the first ten years of the period included in the report. These duties "were not only at all times arduous and severe, but frequently of a most harassing and dangerous character, particularly to the subordinate officers and men. The chief slave-exporting stations were constantly kept under the strict surveillance of one or more cruisers stationed opposite to them; and, whilst so employed, it was not unusual for such vessels to have their boats detached for several weeks at a time, exploring creeks and rivers at perhaps a considerable distance along the coast, or lying concealed under mangrove thickets in readiness to pounce upon the slave craft the moment she shipped her human cargo, or attempted to leave the land. A strict look-out was invariably maintained from each masthead during the day, and from the bulwarks by six men stationed, two on the bows, two in the waist, and two abaft, on each quarter during the night; while the officer on duty was enjoined to scan the horizon with a night-glass every few minutes of his watch."

Between the Gambia and Sierra Leone, generally, a vessel or two has been employed cruising principally off the mouths of the Nunez and Pongos. Formerly, from defective treaties, the cruisers dodged at a distance from land, ready to chase when any suspicious-looking craft made its appearance. For the last ten years, in consequence of more efficient treaties more energetic methods have been adopted, "for, as soon as it has been ascertained that a slave vessel is at anchor in any creek or river, the cruiser either stands directly for her, or should there not be sufficient water, or the navigation too difficult, the boats are forthwith despatched to seize her and bring her out. This latter service, when it is protracted to perhaps several successive days or nights in the vicinity of extensive swamps—and when it is, as it always must be, combined with excessive labour, want of sleep, and irregularity of hours—is, as will be hereafter shown, the cause of a fearful amount of disease and consequent mortality." Fatigue and intemperance have always been the precursors of sickness: either the one or the other will not only predispose but produce fever. In our West India colonies we know that from the rum-store to the

hospital is but a single step: the soldiers being able to procure for a very trifling sum enough of the fiery spirit to intoxicate them first, and give them fever afterwards.

The cruisers on the northern division of the station occasionally visit the Cape Verde Islands, to refresh and recruit the health of the men. The settlement of the Gambia is also frequented for similar purposes. It is remarkable that this place should be as healthy as it is, at certain seasons of the year—bounded, as we find it to be on three sides, by vast alluvial swamps. It has, however, an advantage over Sierra Leone, the temperature throughout the year being somewhat lower, chiefly during the winter months, when the morning air is frequently so sharp and bracing as to require additional clothing. Remittent fevers are always present, but do not become formidable unless contracted under peculiarly aggravating circumstances. From July to October, crews are compelled to seek safety elsewhere, the rains falling in such quantities and at such short intervals as to cause the river to overflow and flood the marshy flats behind the settlement to a great distance. When the river with draws into its proper limits, there are left large shallow lagoons, which, evaporating, become the source of remittent fever of a more virulent character than that which occurs during the dry season. The rivers to the south of the Gambia require the most constant attention of the cruisers: they are the Nunez and Pongos. Only vessels of light draught, or boats, enter them. The streams of these rivers are sluggish; their banks closely fringed with mangrove bushes, around the tangled roots of which there is a thick deposition of blue mud or slime, the detrital sediment of the river water, and mixed with it a large quantity of putrefying vegetable matter. This same putrid mass, left comparatively dry by the receding of the tide and exposed to the heat of the sun, sends forth a most abundant and fetid malaria. It cannot be a matter of wonder that men, on arriving in these rivers from the clear open sea, and with weakened constitutions, should fall an easy prey to the indigenous pestilence of the swamp.

So much has been said and written about Sierra Leone, that we cannot help giving our author's opinions, in his own words, in reference to this portion of the African coast, which has been represented as the charnel-house of Europeans who are compelled to sojourn there for a time. Dr. Bryson states—"That a far greater amount of disease is contracted here by the naval force than upon any other part of the station, at least since the settlement of Fernando Po has been abandoned. It is, also, evident that a great portion of the disease is contracted in consequence of accidental or contingent circumstances peculiar to the locality—from causes common to the whole line of coast, rather than from an increase or an aggravation in the condition of such causes in the locality itself; and of these none seem to operate more powerfully or more frequently than exposure on shore to the intense heat of the sun by day, or to the chilling dews by night, more particularly if accompanied in either case by a state of inebriation, or exhaustion of the physical powers of the body from over exertion." The town, it appears, teems with taverns and grog shops of the lowest description, where intoxicating liquors of the worst quality are sold, or given in barter for the merest trifle. The consequence is that sailors, when they escape only for a short time from the discipline of the ship, abandon themselves to the utmost intemperance and then expose themselves to the burning sun by day; and, exhausted by their debauchery and excesses, throw themselves down to sleep on the naked ground in the bush, or in some obscure corner of the town, until they awake cold and stiff in the morning. Who can wonder that from such excesses, fever results in a tropical climate? The officers and men who navigate foreign vessels suffer most severely, because they are weakened by excessive labour, broken rest, and exposure continually upon the deck of

small vessel, probably crowded with slaves in a loathsome state of disease. Officers and men, once landed, the latter commit outrageous excesses, and most of them pay the penalty by suffering an attack of fever. Refitting ships is another source of disease, because of the intemperance connected with it. The town, however, will always be of importance, from the facilities it affords of sheltering and victualling the ships that put in there. Off Freetown the vessels remain in the open stream, half a mile from the shore, and five or six miles from the nearest point of the Bullom shore. Here there are open woods and cultivated lands; and the little village of Medina is considerably above the level of the river, near which it stands. We can scarcely conceive, therefore, that malaria emanating from this shore could possibly affect the health of Europeans in the vessels, or resident on the opposite side of the river. Moreover, the marsh is cleared; the ground cultivated and dry; and nothing on the southern or eastern side of the town deserving the name of a marsh. Hence the constant succession of sporadic fevers, occurring at Sierra Leone, cannot derive their origin from marsh effluvia, the distance being so considerable that they would become innocuous from their miscibility with the atmosphere.

The rivers Sherbro and Gallinas have banks similar to those of Nunez and Pongos, and a country surrounding them presenting the same physical appearances, and equally injurious to health. Upon the banks of the Gallinas is a notorious slave mart, which renders it necessary to have two vessels generally stationed between Sierra Leone and Cape Mount. The Gold Coast affording no safe roadstead for ships, the crews rarely go ashore, and hence it is difficult to trace the effects of climate upon the naval force employed here. It is supposed to be, however, as inimical to the health of Europeans as any other part of the station within the tropics. The country is hilly, comparatively free from marshes, and the land, with the exception of a few cleared spots around the villages, is covered with jungle. Beyond the Gold Coast is a vast plain, apparently alluvial, through which the river Volta slowly runs: it is shallow and dangerous at the entrance, having a shifting bar across its mouth, and hence seldom entered by our cruisers.

On entering the Bight, the first settlement of any note in this wild region is Quitta, where vessels touch occasionally for provisions. Behind Quitta the branch of the Volta becomes a broad shallow piece of water, with marshy banks covered with grass, gigantic flags, and mangroves. At some distance the country seems fertile. From Quitta to Popoe, and from the latter to Whydah, the shore has the appearance of a low sandy ridge, behind which is another lagoon, of a dark, muddy-coloured, and brackish current, which glides amongst thick reeds and grass, with an almost imperceptible motion, depositing a black ooze most offensive when disturbed. Whydah, situated five or six miles from the beach, is the first great slave mart in the Bight. The river flows behind, and is occasionally fordable; while the road and the town passes through two marshes, and is oftentimes covered with water to the depth of two or three feet. Beyond the marshes the country becomes more elevated. Europeans who visit this part generally suffer severely from fever. Lagoons are nearly surrounded with water, and is considered on a par with the other swampy districts. The Benue, a navigable river, is bounded for a great distance with the impenetrable mangrove swamps, the fertile source of fever. The crews of vessels stationed between Cape St. Paul and Cape Formosa generally suffer less from fever while in this locality than upon any other division of the station; not from superiority of climate, but from having little intercourse with the shore.

The Bight of Biafra next comes under observation—the principal cruising-ground of the squadron—a station eagerly desired because of the number of slave vessels frequenting the many

intricate mouths of the Niger. The coast, however, from heat, humidity, and miasmas, is most prejudicial to health. Prince's Island is a place of exquisite beauty, and is frequented both by officers and men when opportunity offers; nor does it appear that fever is often contracted either in the bay or on the island, except from personal indiscretions. Clarence Cove, on the north end of Fernando Po, is infinitely more unhealthy. This island is represented as being one of the most beautiful on the face of the earth; and, though there are but few marshes within many miles of the settlement, there is not a spot in the whole known world more detrimental to health. The Island of St. Thomas, not often visited, is extremely unhealthy; and so also is Anna Bonita, a pretty little place, free from swamps. Here, in May, 1846, a small schooner anchored, and remained for a fortnight. On the 11th of June the crew put to sea, and before the 20th the whole of the white men, seven in number, died. Two officers and a black were attacked with fever; five died, and three were subsequently invalided. The whole of the Kroomen on board escaped. The Gaboon, though nearly under the equator, and bounded by brackish lagoons and mangrove thickets, is considered the most healthy of the large rivers on this division of the station. The native town of Loango is described as being large, clean, and well built, yet with a climate fatal to Europeans. The waters of the Congo, which the ships take on board, is at first of a reddish colour from impurities, which, however, are soon deposited, and it then becomes clear and wholesome; if drunk when impure or brackish it is apt to produce intestinal complaints, which may degenerate into dysentery. At St. Paul de Loanda fevers prevail somewhat different to the remittent of Sierra Leone, being complicated with a certain amount of intestinal irritation; they terminate frequently in true intermission. Smallpox is rare, but attempts to introduce vaccination have hitherto failed. The native blacks are not subject to fever, but are liable to diarrhoea, dysentery, and dilatation of the rectum. Benguela is considered to be the most sickly of the Portuguese African colonies south of the equator. It is situated on an alluvial flat at the upper part of the bay, with a range of lofty hills at some distance in the rear of the settlement. It is extremely hot, and is destitute of water, with the exception of that brought from a small stream a few miles north of the town, which flows through a marshy flat into Sobito Bay. Old Benguela is the most fertile and park-like land on that part of the station. The harbour of Little Fish Bay (in Portuguese, Massamedes) is landlocked, and abounds with excellent fish. The banks of a small stream which flows into one side of the bay are extremely fertile, and under cultivation. The climate is thought to be healthy.

We have thus given a brief sketch of this interesting chapter, in order that the subsequent part of the work may be understood; to this we shall refer at an early opportunity.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein Carfrae, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

Beta.—The Arabian estimate of female beauty is given by Mr. Kay, in No. 107, as follows:—"Four things in a woman should be black—the hair, the eyebrows, the eyelashes, and the iris of the eyes; four white—the complexion, the white of the eyes, the teeth, and the lips; four red—the tongue, the lips, the middle of the cheeks, and the gums; four long—the back, the fingers, the arms, and the legs; four

round—the head, the neck, the arms, and the ankles; four wide—the forehead, the eyes, the bosom, and the hips; four delicate—the nose, the eyebrows, the lips, and the fingers; four ample—the lower part of the back, the thighs, the calves of the legs, and the knees; four small—the ears, the breasts, the hands, and the feet."

Kif.—We are sorry for the omission. The numbers shall be duly forwarded. We thank our correspondent for the promise of the interesting papers, which will receive all due attention from us.

A Legally-qualified Practitioner, London, writes as follows:—"Upon reference, I find that a gentleman examined in Dr. Cormack's case, on his behalf, calls himself a 'Medical Doctor;' I refer to the 'Medical Directory,' and find the person put down as one practising without any qualification. In justice to himself, Mr. Wane should inform the readers of your valuable journal who and what he really is."

O. L. U. asks (in reference to an answer given to Medico-Chirurgus, that there is no law to prevent a licentiate of the Hall practising any branch of the profession)—"Is not every one who practises physic without a license from the College of Physicians infringing their charter? and what clause in the Apothecaries' Act entitles an apothecary to practise physic?" The certificate declares that the candidate has been examined "in the science and practice of medicine;" and we conceive that the general practitioner does not infringe the Physicians' Charter in prescribing for medical diseases.

Bostonian, Boston.—The Editor of the Pharmaceutical Times will give our correspondent every necessary information in reference to the "new process of the Abbé Baldannek."

S. D.—The former letter being destroyed, we are not certain to what our correspondent refers. If to "Tartar on the Teeth," the authority is Mr. Hassall, in Part IX. of "The Microscopic Anatomy of the Human Body."

Phlogosis would, no doubt, like his communication to be published, but we should not like an action for damages.

Candidus.—A letter had better be forwarded to the publishers, who will perhaps state the reasons why the publication is delayed. It is a matter not within our province to discuss.

Questor.—The communication is now lying at our office, which may be obtained on application. The mass of letters now lying before is so great that it could not be inserted for a considerable time, and then not without curtailment.

A Hater of Humbug.—We like to exercise charity; the "fouting" and puffing of the parties are well known, not only to us but to the whole profession.

A Pupil.—Medical jurisprudence is a most important part of professional education, which should not be neglected. The best work is "Dr. Guy's Medical Jurisprudence."

Medicus.—The symptoms of perforation often come on very suddenly after eating a large meal. Violent abdominal pain, vomiting and great prostration of strength, generally followed in a few hours by death. Cases have occurred, however, in which patients have survived for months. Dr. Seymour mentions two cases which came under his notice in St. George's Hospital: one survived the perforation five months, and another twelve days, after the most violent symptoms of peritoneal inflammation.

Stephanas.—The communication has been acknowledged, and we regret that we have not yet been able to find a place for it in our columns; we hope to do so shortly.

Mr. Oldfield.—The parties are liable to prosecution under the Apothecaries' Act, they are arrant quacks, and the Society, we should think, would feel an honour to rid the place of such mountebanks.

Dr. Bessborough.—The paper shall have an early insertion.

An Injured One.—Such acts of injustice will, before long, meet with their reward. The profession will not be ridden over "rough-shod" by guardians "who are celebrated for large stomachs and small brains."

S. T. Jepson.—The fee cannot be recovered, the magistrates having no power in the matter.

Philo.—We are not aware that the Government has determined on doing justice to navy assistant-surgeons. We shall not fail to use our best endeavours to promote the good work.

Omicron.—The interest has subsided, and we must, therefore, decline to insert the letter.

Rusticus.—A knowledge of Latin is requisite. Celsus and Gregory are the two works read at the Hall, with the London Pharmacopæia and Physicians' prescriptions.

Sam Slick.—Witty, but inadmissible.

A Member of the National Institute.—We must refer our correspondent to Mr. Ross, Hanover-square Rooms.

A Surgeon, Portsmouth.—If our correspondent will forward us a communication in reference to the shabby treatment of the insurance-office to the medical gentleman, it shall be published.

O. D.—Patience, perseverance, and promptitude will certainly accomplish all that is desired.

Will Dr. R. G. D. be kind enough to forward us the newspaper to which he refers? The other suggestions shall be attended to.

Mr. W. Brown, Surgeon.—We will endeavour to accommodate our correspondent at an early opportunity.

A Subscriber wishes to be informed "how to go about obtaining a German degree, or what college, or head of what college, to write to on the subject."

Krites is thanked for his information. We shall not fail to advocate the interests of the profession whose approbation is expressed in the great sale of the Medical Times.

Letters and communications have also been received from Candidus; Phlogosis; S. D.; Questor; Rusticus; Philo; Omicron; S. T. Jepson; An Injured One; Dr. Bessborough; Mr. Oldfield; Stephanas; Bostonian, Boston; O. L. U.; A Legally-qualified Practitioner, London; Kif; Beta; Sam Slick; A Member of the National Institute; A Subscriber; Mr. Brown; Dr. R. G. D.; A Hater of Humbug; A Pupil; Medicus; Krites.

THE MEDICAL TIMES.

SATURDAY, JULY 3rd 1847.

THE GOVERNMENT ANSWER TO THE IRISH MEDICAL PROTEST.

We are inclined to suppose that the rousing up of the profession to activity in order to obtain that which is their due is a matter of no small surprise to the members of the Government. It is evident they have long thought that medical men had no clear views of what constituted their rights, and that they would never exhibit union and moral courage sufficient to assert them, if understood. Acting upon this opinion, Sir J. Graham, during the time that he was Secretary at the Home-office, very coolly introduced a bill into the Commons House of Parliament for more effectually degrading general practitioners; and when some of the said parties, to the number of 3000 or 4000, for whom he so kindly offered to legislate, came thundering at the office door, and importuned in such a way that there could be no mistake they intended to fight for their lives, the honourable baronet was lost in wonder and astonishment. He had been so well crammed by the two royal colleges in London, that he was led to believe it would be an unparalleled act of generosity to let loose upon the general practitioners the whole pack of quack bloodhounds, to hunt down and destroy them without any mercy. They were considered little better than a flock of sheep—easily scattered and worried, without uttering any cries of lamentation in the midst of their sufferings. Though they have been spared through the ex-

ercise of an indomitable courage, it appears as if the Executive had not yet been taught the value of their services, the army surgeons being denied the honours to which they are entitled, and the navy assistants left to companion with beardless boys, in that plebeian apartment of a man of war denominated the gunroom. The surgeons of the empire are everywhere treated with a sort of left-handed liberality—receiving the lowest possible remuneration for most valuable services.

At the present moment the profession in Ireland is smarting under the insults which it has received from official persons, and, as we have already stated, have sent in a dignified remonstrance to them. We purposely refrained last week from bringing before our readers the answer which had been received from the Castle to the protest signed by upwards of a thousand physicians and surgeons of Ireland, among whom are names of some of the most illustrious medical men in that part of the empire. The reply exhibits a frigid indifference to the just claims of the memorialists, and leaves them the alternative of either accepting the mechanic's remuneration of five shillings a day, or of further troubling themselves by applying to the Lords Commissioners of her Majesty's Treasury. The following is the official document referred to:—

THE REPLY.

"Dublin Castle, July 14, 1847.

"SIR,—I am directed by the Lord Lieutenant to inform you, with reference to your letter of the 9th instant, that by the Act 10th Vic., c. 22, the salaries of the medical officers appointed under the 9th Vic., c. 6, are subject to such regulations as may be made by the Lords Commissioners of her Majesty's Treasury, to whom, therefore, his Excellency has forwarded the memorial to which you refer.

"I am, Sir, your most obedient, humble servant,

"T. N. REDINGTON.

"To W. R. Wilde, Esq., 15, Westland-row."

From this brief letter we arrive at the following conclusion:—That the members of the medical profession are despised by the Government. The facts stated in the memorial were considered unworthy of notice. All the zeal and efficiency which have been manifested by medical men in the discharge of their duties have been passed over in silent contempt. No word of commendation is found for those who have jeopardized their lives and health in the cause of suffering humanity, at the time when Government was paralyzed at the prospect of the stupendous calamities which threatened the sister country. The starving multitude could not be adequately fed; and when disease, the inevitable consequence of famine, invaded the land, hope rested on the members of the medical profession, who, like the little band of Gideon's army, were to deliver their country from the power of the enemy. When a call was made for their assistance, who amongst them were found fearful or faint-hearted? Not one. When any fell, others stepped in to stop up the gap; and, though fever has made fearful havoc amongst their numbers, they are as courageously and zealously as ever engaged in their work. The Government might at least have given to such faithful servants an approving "well done," though it might have found excuses to have withheld any further pecuniary bounty for such important services beyond the five shillings a day. When Athens was visited by a direful pestilence, and the "father of physic" employed his skill to check its ravages, a grateful people and Government inscribed his deeds in the

archives of their republic, and thought it but a small token of gratitude to bestow upon their deliverer a golden crown; but the authorities of Dublin Castle, in the nineteenth century, cannot spare time, ink, and paper to notice the excellent deeds of the members of the profession whose skill in the treatment of disease is as infinitely superior to the Athenian deliverer as the light of noon to the first ray of the morning.

In "the reply" the memorial is hardly mentioned, and we should judge from the phraseology employed that his Excellency never read it, but forwarded it unopened to the Treasury; and by this time, in all probability, it has been employed for the ignominious purpose of lighting the kitchen fire. So much for medical memorials signed by rank and talent. Our profession is evidently plebeian in the eyes of some aristocrats, and, as a consequence, it is treated with contempt.

We infer, moreover, from the answer that the Government sets the medical profession at defiance. Mr. Wilde is commanded to take the Act 10 Vic., c. 22, and divide it in *partes equalles* for the 1106 gentlemen, to be taken by each as a pill to cure all their complaints. We have heard, however, upon pretty good authority, that not one has been able to get it down, and that as it is now sticking in their throats, producing the greatest irritation, the members of the Board of Health are forthwith to use the probang to make the gentlemen stomach it.

The great grievance of which the profession complains is inadequate remuneration for responsible and dangerous duties:—"Where the amount is left to the discretion of Government, or to the award of officers in public departments, it is often unjustly and degradingly inadequate;" and the official note in answer holds out no prospect of redress. The members of the Executive treat with scorn all medical protests and combinations: the former being considered as mere harmless missiles, and the latter as containing the elements of their own speedy destruction. They have drawn these conclusions from the past history of the profession: its different sections, like the petty states of the ancient Grecian republic, have exhibited too frequently an inveterate jealousy towards each other, and a reprehensible alacrity to wage war amongst themselves for the most trifling provocation. Common dangers have united them temporarily together, but, these once passed, they have relapsed into the same pugnacious spirit. We trust, however, that such a state of things has now for ever passed away, and that, if enemies count upon the internal dissensions of the profession to bring about its own humiliation, they will henceforth be disappointed. A former Home Secretary felt himself balked in attempting a one-sided medical legislation, and it may be that the Lords Commissioners of her Majesty's Treasury may be doomed to the same thing in their endeavours to force the Irish medical practitioners to accept of five shillings a day for the exercise of their skill and the perilling of their lives. Mr. Trevelyan, of the Treasury, may threaten to send over surgeons in the pay of the Government to coerce the refractory into submission; but the proposition is more easily made than carried into execution, if the profession is true to itself.

In conclusion, we would earnestly press upon medical practitioners the necessity of uniting to secure a due respect for their calling, and a just reward for their services. An honourable emu-

lation amongst themselves will be no barrier to this, while it will enforce respect from those who now treat their remonstrances with short and unceremonious replies. And we would further urge upon the profession the necessity of using efforts to introduce some of its members into the British House of Commons. There they have been hitherto unrepresented, and, as a natural consequence, their interests have been little cared for in the deliberations of that august assembly. France has set us an example which ought without delay to be imitated by us, and then we should not fail of procuring from the Government a sound measure of Reform, and substantial tokens of reward for our services.

POOR-LAW GUARDIANS AND MEDICAL OFFICERS.

We last week published a document in reference to the treatment of the medical officers of the Halifax Union by the board of guardians. It is a summary of visits and medicines supplied to poor-law patients for a period of thirty-one days; and from this we learn that the scale of remuneration is equivalent to 3½d. for each visit, the medical officer having also to supply, for this sum, the requisite medicines. We must acknowledge that the publication of this document has caused us to feel mixed emotions of pleasure and pain—pleasure that the medical gentlemen have resolved to hold up to public view and reprobation the injustice which they experience from the hands of the Halifax poor-law functionaries; and pain that any set of men could be found, called especially by the name of "guardians," who could act so unjustly and cruelly towards their medical officers, as to give them for each visit to a sick pauper the pitiable sum of threepence threefarthings, for which, also, the doctor was expected to furnish medicines. This is the reward for all the skill and patience, and forbearance, and defiance of personal danger which he exhibits; for being brought into contact with the most frightful diseases; and for exposing his life in attempting to arrest its progress, and preventing its dissemination. The Halifax medical officers, touched with a sense of the wrongs inflicted on them, met, on the 6th of the present month, and unanimously passed resolutions, urging in one of them the board of guardians to give them the very moderate sum of 7s. 6d. per case—renewable, in long-continued ailments, every three months. Here was nothing like an unjust demand, and yet there was a guardian with ignorance and impudence enough to propose that the resolutions should be treated with "silent contempt." Such an insult, coming from a low-minded individual, must have been keenly felt by the gentlemen of education for whom it was intended; while it shows that guardians of this stamp, who would take from off their own shoulders the burden of maintaining the sick and place it upon those of the medical attendants, can only be effectually punished by the members of the profession combining together, and fixing the lowest amount of remuneration which they will receive for their parochial duties.

It is to the honour of the medical profession that its members have ever manifested the most benevolent feelings in their attendance upon those who have from their poverty been unable adequately to remunerate their important services; and we trust that the same noble principles will be ever cultivated and displayed. It is for this very reason we strenuously advocate, from time

to time, public acts of justice towards them, that in the discharge of professional duties they may have no barriers placed in the way of exercising the best feelings of our nature, which it is their glory to cherish. The public, in acting unjustly towards the medical profession, is not true to itself; many instances being within our knowledge of individuals becoming permanent burdens on society from the exercise of an unwise and unjust parsimony in official persons. Not seeking the means of obtaining early relief for them. Nothing is more characteristic of a high tone of moral feeling amongst a people than the care which they manifest towards those who have the misfortune to be poor: for their comfort humanity suggests that every provision should be made, and when sickness invades, that no means should be left unemployed to mitigate its virulence and arrest its progress. Hitherto, in this country, it has been thought enough for parishes to grant a niggardly pittance for the support of paupers while in health, leaving to the members of the medical profession the care of them in sickness, without the prospect of anything like adequate remuneration for their efforts. Infinitely better would it be that they at once should make their attendance on the parish poor a "labour of love," with a clear understanding that it is so, than that they should be badly paid and badly treated by poor-law guardians and Government authorities.

The third resolution at the Halifax meeting ought not only to be read by every medical practitioner, but by all parish and Government servants throughout the kingdom; it is as follows:—"That in the opinion of this meeting the public services of medical men are neither properly understood nor duly appreciated, and the award made to them is on a scale wholly incommensurate with the amount and importance of the duties they have to perform. That the stipend they receive does not place them on an equality with an inspector of police, notwithstanding which they are compelled not only to furnish medical advice and attendance, but to supply all necessary appliances and medicines. That the smallness of the stipends now awarded makes it clear that the medical relief of the poor falls, not on the board of guardians, but, very unjustly, on the hard-worked medical officers."

The sooner this state of things is brought to a close the better. It has been too long the fashion to expect medical men to give their services for nothing, or next to nothing. The lawyer cannot sign a document without a fee; the parson cannot preach a sermon without an offering; but the surgeon may physic and bleed and blister "for the love of God," to all eternity, without one offering being cast into his treasury. As long as he chooses to submit to this, the oppressor's hand will be upon him, and his own efforts will alone remove it from him. We are glad, therefore, that the meeting to which we have alluded pledged itself in the sixth resolution "to uphold by every means in its power the honour and dignity of the profession, and on all occasions to advance its best interests and to promote the welfare of every member, thus hoping to receive the approval and support of their brethren at large."

There is something about this resolution truly admirable—it only wants such feelings as are here embodied in words to be generally experienced, to hasten on the jubilee of the profession. Let its members once feel they are "brethren," and be determined to promote the welfare of "each other," and they will then speedily emancipate

themselves from the degrading thralldom of thick-headed poor-law guardians, and will receive from all classes of the community a just reward for their labours.

MEDICAL APPRENTICESHIP.

It was considered necessary by our forefathers that the *alumni* of the profession should be articulated to experienced medical practitioners for a limited period, in order that a knowledge might be acquired of the various articles of the *materia medica*, as regards their properties, preparation, and composition.

The wisdom of the ancients in thus causing the medical youth to undergo this kind of professional bondage has been recently called in question, and powerful efforts have been made to do away with the system of apprenticeship. It has been represented as degrading in its influence, a waste of valuable time, and a sort of discipline to which young men ought not to be compelled to submit. We allow that powerful objections have been urged against it, and that there are many things connected with it which demand revision. It was formerly the practice of requiring a pupil to serve his master for the long period of seven years. The Apothecaries' Act made an innovation upon this ancient requirement, and five years are only now demanded by law. This, however, we consider too long a period to be "behind the counter," and few medical gentlemen now enforce all that is commanded by act of Parliament. It is a question, however, if the entire abolition of apprenticeship would not be productive of much that is injurious, as it is well known that much useful knowledge may be imparted during this period by an intelligent master, which prepares the way for the cultivation of those branches of medical science taught in schools and hospitals.

Mr. Martin, of Reigate, has drawn the attention of his professional brethren to this subject in a paper which he read at the annual meeting of the South-Eastern Branch of the Provincial Medical and Surgical Association. He considers that the only real objection against apprenticeship is its length, and that, the time being shortened, it is an institution which ought not to be cast aside as worthless. He thinks that during this period a good knowledge of the various drugs employed in medicine may be acquired—a readiness and quickness of manipulation, and an accuracy and perfection in the combination and preparations of medicine. He, moreover, considers that a useful knowledge of therapeutics may be furnished to the pupil in private practice by the observation of disease and the manner in which it is treated. It is also a valuable time for reading, not, as he observes, "the mere manuals and class-books," as being the short cuts to knowledge, but the works of authors of the highest repute in medicine. The concluding remarks of his address are worthy of especial attention. "I am," he says, "desirous of vindicating the *dignity of labour*; of asserting that the education of the senses, and the education of the hands and fingers, as well as of the head, is perfectly consistent with the highest refinement of mind and manners, and the most gentlemanly conduct. Such has been, in fact, the course of early discipline through which have passed some of the most eminent men who have dignified and adorned our profession."

In these times of innovation, medical practitioners should be especially careful not to demand any change which experience has not

proved to be necessary. In the matter of apprenticeship, it would be well for them very seriously to consider its advantages as well as its disadvantages, and only to demand its entire abolition if the latter are found to prevail.

GOSSIP OF THE WEEK.

UNIVERSITY OF LONDON.

MATRICULATION.—1847.

Examination for Honours.

MATHEMATICS AND NATURAL PHILOSOPHY.

Routh, E. J. (exhibition), University College; Alder, E. H., University College; Bridge, J., University College; Gillett, J., private tuition; Malleison, W. T., University College; Clair, J., Stonyhurst College; Giles, W., St. Edmund's College, Ware; Bamber, J., St. Edmund's College, Ware; Johnson, J., Stonyhurst College; Odling, William, Guy's Hospital; Ray, J., Wesleyan Coll. Inst., Taunton; Chambers, B. E. C., Wesley College, Sheffield.

TYPHUS FEVER IN LONDON.—Typhus is still on the increase in this town. During the past week about twenty cases have been removed from Wellington-yard to the Fever Hospital, though every possible preventive and remedial measure had for some time previously been resorted to. It is a melancholy gratification to learn that this seat of disease (Wellington-yard) is now entirely cleared of its inhabitants. Mr. Whitehead, chief clerk at the Board of Works, has taken possession of every dwelling, eighteen in number, and it is intended that they shall not again be inhabited for the space of three months—an interval which will be occupied in thoroughly whitewashing, cleansing, and purifying them. The Rev. W. S. Monck, and Mr. Samuel Sharp, surgeon, have become victims of the fever. We have also to add to the list of those sick, Mr. Richard Hodgson, assistant to the borough surveyor, who, it is supposed, caught the fever whilst attending to his duties in Shannon-street. The police who were ill are improving, and the assistant of Mr. Bulmer, surgeon, is likewise progressing satisfactorily towards recovery.

METROPOLITAN SOCIETY FOR THE ABOLITION OF BURIALS IN TOWNS.—On Wednesday week, a meeting was held in the Society's rooms, New Bridge-street, Blackfriars, Mr. G. A. Walker, surgeon, in the chair. Messrs. Atkinson, Harting, and other gentlemen, adduced several instances of the fatal effects of inter-mural burying, which practice they denounced as being as injurious to morals as it was to public health. It was ultimately resolved to circulate, through the medium of the press, facts illustrative of the evils of inter-mural burials; and also to call a public meeting upon the subject at the close of the ensuing elections.

MILBANK PENITENTIARY.—WOOLWICH HULKS. Mr. T. Duncombe called the attention of the House to the reports laid before Parliament during the present session, of the state of Milbank Prison, and the treatment of convicts on board the Hulks at Woolwich. The reports on the state of the Penitentiary showed that the prisoners were in a most deplorable state, that scurvy prevailed amongst them to a great extent. He hoped the Government would bring in a bill to put this prison on an entirely new system. The Hulks are in an equally deplorable state.

SICKNESS AND MORTALITY AMONGST EMIGRANTS.—From the 21st of April to the 27th of June inclusive, 74,181 emigrant passengers arrived at New York, of whom 2078 were admitted into the Marine Hospital. Of those admitted, four per cent, or 197, died; 1227 recovered, and were discharged.

BRITISH MUSEUM.—The British Museum Commission has adjourned for three months.

MUNICIPALITY.—M. Van Cuneghem has left 100,000 francs for the erection of a hospital for the blind at Guid.

NAVAL APPOINTMENTS.—Surgeons: Hugh Jameson, to the Victory; and David Giddes, to the San Joseph.

OBITUARY.—July 17th, at Leeds, aged 40, Francis Sharpe, Esq., of fever, caught while discharging the duties of district surgeon, which he had undertaken during the illness of Mr. Taylor.—July 19th, Richard Morice Tobin, M.D., surgeon, of Her Majesty's Dockyard, Devonport.

—Late at Lynn, John Wayte, Esq., M.D., aged 68. He was an alderman of the borough; twice mayor; formerly physician to the Lynn Dispensary, and also senior physician to the West Norfolk and Lynn Hospital. He died much respected, particularly by the poor, to whom he was always a ready professional friend.

—Late at Ballyfarnham, of fever, — Hawkesworth, M.D.—July 14th, at Nenagh, of fever, aged 27, J. B. Fletcher, M.D., one of the physicians of the Nenagh Fever Hospital.

—July 2nd, at Waterford, of fever, John Price, Esq., M.D.—July 7th, of fever, R. B. Barlow, Esq., one of the union surgeons for the Blackburn district.—On the 12th instant, at his residence, Bronte cottage, Walton-road, aged 61, John Turner, Esq., M.D.—On the 10th of February, at his residence, at Dover, United States, aged 40, Mr. Ellis Sweetlove, member of the Royal College of Surgeons, and licentiate of the Apothecaries' Company, London.—On the 24th inst., at Salford, Walden, Thomas Mickle, Esq., surgeon, aged 38.—On the 26th instant, in Stanhope-street, Regent's-park, three days after his arrival from the United States, Arthur Clark, Esq., M.D., youngest son of the late John Clark, Esq., formerly of Poole, in the county of Dorset.

MORTALITY TABLE.

For the Week ending Saturday, July 24, 1847.

COURSE OF LECTURES ON CLINICAL MEDICINE,

Delivered in the THEATRE, QUEEN'S COLLEGE, Birmingham.

By **S. WRIGHT, M.D.**

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and formerly Senior President, of the Royal Medical, Royal Physico-Medical, and Cuvierian Natural History Societies of Edinburgh, &c.

Case of gastro-intestinal disorder; extent and variety of these cases; value of recording them; case under present consideration first admitted for simple fever; superposition of local congestion of the brain; treatment; recovery; persistence of paralysis after the probable cause of it had been removed; observations upon this subject; subsequent illness of the patient; readmission into the hospital, suffering chiefly from paralysis with cerebral disorder; detail of the symptoms; comments upon them; treatment; relative effects of different remedies; efficacy of the oxide of silver; another case of seeming cerebral disease that resisted every tried remedy except the oxide of silver, under which it recovered; observations.

GENTLEMEN,—You have seen an extraordinary case of gastro-intestinal derangement, with various morbid sympathies, treated by me during the last few months. I will give you its details with some running comments. I am not intending to make this a discourse upon dyspepsia in general; were I to do so, and do the subject even in indifferent justice, my lecture must transgress all ordinary limits. The nosological position of indigestion and its complications is, as you are aware, a very prominent one. Than these ailments, there are none more numerous, or more diversified, in the great catalogue of "ills that flesh is heir to." Your daily experience will introduce you to fresh varieties of them, but you may become patriarchs in your profession without knowing the whole. Hence the value of recording any cases in point which are fertile in features of practical interest: they are so many sources of instruction not only to pupils, but also to practitioners who meet with them for the first time. It is this consideration which disposes me, with very little enlargement upon actual detail, to occupy your time to-day with the strange case I have alluded to.

The subject of it, was a woman named Mary Ann Frost, who first came under my care on the 5th of November last year. She was thirty-two years of age, and the mother of three children. She was admitted suffering from simple fever, and under a very simple form of treatment recovered rapidly, until one day, about a week after her admission, when we found her complaining of a severe dull pain on the right side of the head, and slight numbness of the left arm and leg. The right pupil was more dilated than the left, and less sensible to light than natural: it not only did not contract as much as it ought under the influence of light, but it did not begin

to contract one or two seconds after strong artificial light fallen upon it. The pulse was 90, and sluggish not hard; the tongue had become furred the last twelve hours; sickness had also subsided; and there was some epigastric tenderness. The head was not strongly hot; there was restlessness, watchfulness, or irritability; no of the eyes, or vascularities, or intolerance; no ringing in the ears, or any of the other symptoms indicative of inflammation, commencing or commenced, in the brain or its membranes added to these negative testimonies, the character of the pain and the condition of the referred to local congestion of the brain, passive than active in its kind. The sluggish pupil was another reason why I this diagnosis: in active cerebral congestion inflammation, you have generally at the commencement a contracted pupil.

Looking at it in all its bearings, and considering the type of the prevailing fever to acquire the depressed type, I thought it advisable to employ measures as mild as I could, consistent with the state of the patient, and the progress of its becoming worse. The object was to remove the present congestion, but not its recurrence. To this end six leeches were ordered to the seat of pain, and to be followed by a blister at the back of the neck, if the symptoms were not relieved in two hours. Five grains of calomel were given immediately, and a purgative shortly afterwards. I visited her after a few hours, and found her somewhat relieved. The enemata had dislodged a quantity of mucus and scybala of feces, and the calomel procured a copious bilious dejection; yet, in consequence, were less tense and than in the morning. The leeches bled and produced a decided elevation of the pulse was more free and a little slower, but there was no perceptible alteration in the paralysis of the left side. This diagnosis: in the living economy, the cause being taken away, "does not always apply. We meet with vital impressions continuing to speak—that is, the impression having made, the original source of it may be without the impression coincidently. In nothing do we see this more than in disorders of the nervous system produced upon

this system, in whole or in part, are often not easy of subsidence. In the case before us, it was quite clear that the depletive and derivative actions had greatly lessened, if not removed, the local congestion, yet one of its most delicate manifestations—the diminished sensibility of the pupil, and of the organs of locomotion on the left side—had scarcely undergone any change. The persistence of this morbid effect was, no doubt, due to the continuance of the impression which the overcharged vessels had made upon that part of the brain where their pressure had been exerted. I told you that it was not improbable a night's rest would aid the organ to recover its original condition and tone. So it did. The next morning the patient had little complaint to make, except of weakness. The pupil was not quite natural, but so nearly so as to be of no consequence, and the numbness of the left side was all but gone. For two or three days subsequently we merely attended to the state of the bowels, and kept the patient quiet. During this time she continued further to improve, and then we gave her a light vegetable tonic with an alkali, and an aperient pill at bed-time. Under this plan she fairly recovered, and within a month from the date of her admission she left the hospital well.

Some weeks afterwards she again became the subject of severe headache and partial paralysis, for which she was attended by a neighbouring surgeon for a time; but not improving she consulted another, and was under his care several weeks, gradually getting worse. A gentleman in this class kindly called upon me one day, to give me a description of her state, and to inquire whether I should again like to have her for a hospital patient. Judging from his report, which was intelligible and accurately given, the case seemed a hopeless one, but of course I could have no objection to receive it, and accordingly, on the 21st of March last, Mrs. Frost was again admitted under my care. Not having seen her during the previous three months, I was certainly very much struck with her altered appearance when we met at her bedside. She was greatly emaciated; cheeks sunken and bloodless; eyes hollow, surrounded with a dark areola, and each inclined towards the nose, constituting a very marked squint. This deviation from parallelism had existed for more than a month, and caused her to see every object double: in whatever situation I placed myself, she said she saw two Dr. Wrights. Pupils dilated, and imperfectly

sensible to light. Her general strength was greatly impaired, but her right arm and leg were almost completely paralyzed; she could not close her hand, or lift it more than a few inches above the bed; she could raise her foot about the same distance. There was slight paralysis of the left side of the face, and articulation was thick and indistinct. She complained of a constant, dull, throbbing pain on the left side of her head, extending from the temporal to the cerebellar region: this pain had existed for more than two months. Her other chief complaint was, a feeling of weight at the epigastrium, and excessive flatulence. The frequency and force of the eructations plainly confirmed this. She had scarcely any appetite; tongue completely covered with a thick white fur like flannel, trembling, and remarkably indented at the edges; skin soft and flabby, and constantly bedewed with a cold clammy perspiration; pulse 86, small, and very feeble; systolic sound of the heart scarcely audible; urine scanty, and high coloured; bowels obstinately costive, faeces lighter than natural.

These were the general features of the case; and, as I told you at the time of seeing them, they were quite sufficient to give us rational grounds for apprehension for the patient's safety. The cerebral symptoms, the paralysis, and the squinting, and the length of time these had lasted, naturally pointed to the probability of some disturbance in the brain. The symptoms told us that this suspected disturbance was not active, but it still might be serious, and even fatal. I confess that, at the first view of the case, I thought it hopeless, and I told you so. At the same time I told you that it became us not to let untoward apprehensions paralyze our energies, but rather prompt us to seize what few opportunities we had for affording relief to the sufferer. It was quite clear, as I have said, from the nature and duration of the severer symptoms, that whatever cerebral mischief might exist was not marked by activity. There might be local inflammation in the substance or the meninges of the brain; but if there were this, it was very mild and modified in its kind; there might be passive congestion, slowly increasing; or thickening of the membranes; or tubercular or other deposits; or bony accretion pressing upon the brain; or softening of this; or extravasation within its substance—any of these, or other morbid states, there might have been, as the sources of the manifest mischief which the poor patient exhibited. These were the most unfavourable views of the case for us to take; but there were some suppositions of encouragement, withal. It was far from improbable that the condition of the brain might have sympathetically occasioned the debilitated, depraved state of the stomach. A furred tongue, loss of appetite, flatulence, and constipation, are common coincidences or consequences of disease of the brain. But perhaps the opposite more often holds. There is no limit to the sympathy that obtains between the brain and the stomach, when the latter is the organ primarily affected. The instances are numberless of suspected cerebral disease finding its cure in a course of tonics and aperients. We at least, then, had some hope, and this was strengthened by the state of the pulse and the general debility. Local paralysis may exist without a diminution of power in other than the paralyzed parts, or any failing in the force and frequency of the pulse. It was this general weakness and debilitated circulation that led me to hope we might remedy the ailment through the organs of digestion. This was certainly the only view in which we could see a chance of the patient's safety, and I, therefore, determined to act upon it.

Depletion was, of course, out of the question, but I thought we might venture upon counter-irritation, if not with benefit, at least without disadvantage.

A blister was, therefore, applied behind the ear on the affected side, and directed to be kept open by a dressing composed of equal parts of canine ointment and strong mercurial ointment.

The state of the bowels demanded an immediate and not very mild remedy, which was furnished in the following pills:—

R. Pil. coloc. c. 3ss.; ol. crotoni m. iij. Misce intime et divide in pil. vj. quarum capiat j. tertia quaque hora donec alvus respondeat.

Hoping, rather than believing, as I have said, that the stomach was at fault, I determined upon a tonic mixture. The excessive flatulence, flabby tongue, weak pulse, and relaxed state, suggested ammonia, and the following mixture was given:—

R. Inf. gentianae comp. ʒviij. i. smul. carb. ʒij. M. ft. mist. cujus cap. coch. ula duo ter die.

She was ordered beef-tea, twice daily, a mutton chop; if she could eat it; for deer, and arrowroot for breakfast.

On the 22nd we found her in much the same state as before. Her blister had risen well (this was an encouraging circumstance), as was very inflamed from its dressing. The bowels had been freely opened, and the mixture had acted upon the stomach (as the patient said), and abated its flatulence, without producing any unpleasant feeling. Contr. mist. et pil. pro re.

21. No perceptible change, except that the motions are deficient in bile. Cap. hydr. chloridi gr. v. et contr. altera remedia.

27. No alteration, except that, late at night, she was seized with severe tenesmus, and a very violent purging. The tenesmus was still troublesome, she was ordered a cathartic enema with forty drops of tincture of opium. The pills to be omitted, and the mixture continued as before.

28. Complaints of great restlessness, and want of sleep: sees "sparks falling in the air," and various spectral figures; wanders continually, and in the night hooted vociferously. Flatulence very distressing; says her stomach is cold, but is relieved by the mixture. Contr. mist. et adde ad cam sp. ʒss.

R. Hydrag. chloridi, gr. ss.; M. ft. q.s. ut it. pil. Cap. omni nocte mane et ante coenam the feet immersed in hot mustard water every night.

31. Little alteration; flatulence still distressing. The blister to be dressed over the navel only; the mixture to be continued as before.

R. Hydrag. chloridi, gr. ss.; M. ft. q.s. ut it. pil. Cap. omni nocte mane et ante coenam the feet immersed in hot mustard water every night.

Up to April 10 she continued in the same state; one day being a little better, and another day rather worse, and scarcely any at all. On this day she repeated behind the ear, and the pills to be substituted by the following:—

R. Pil. coloc. c. ʒss.; M. ft. pil. cap. omni nocte.

The gums were slightly affected, no benefit resulting from it, the treatment was discontinued.

17. No change, except that the debility has increased; patient very quiet, and especially with the nurse, whom she regards as a special enemy; has strange religious notions, and keeps her fellow-patients in incessant ejaculations and prayers.

R. Inf. caspariae ʒviij. i. smul. carb. ʒij. tinct. hyoscy. ʒij. M. ft. mist. cujus cap. coch. ampla duo ter die.

Up to the 20th she improved very slightly with this change of medicine. However, she retrograded, up to the 24th, and additionally to her other ailments, she was seized with severe shooting pains, seemingly in her stomach. The pills suited her, and were therefore continued, with the same solution.

R. Inf. quassiae ʒviij. i. smul. carb. ʒij. tinct. hyoscy. ʒij. M. ft. mist. cujus cap. coch. ampla duo ter die.

The solution of strychnine in the mixture is from a formula I use at the Hospital; the dose given is equal to one-sixteenth of a grain.

This change was produced by the fact. The

paralysis of the leg was certainly a little better, but the arm remained the same, and the squinting, pain in the head, and hallucinations were unchanged.

On the 27th she became excessively uproarious, swore horribly, and, with the arm and leg that she could use, kicked and struck the attendants until they were obliged to pinion her. At ten o'clock at night I was summoned to the hospital to see if she had better not be conveyed to an asylum. I ordered her five grains each of hyoscyamus and camphor, and the strait waistcoat. The pills composed her, and the next morning she was very quiet, but excessively prostrate. The pills were directed to be again given at bedtime, and the following mixture was substituted for the strychnine:—

R. Ammon. carb. ʒij.; sp. eth. sulph. ʒij. i. mistura camphorae ʒviij. i. M. ft. mist. cujus cap. coch. ampla duo quartis horis.

This mixture afforded her some relief. You remember how she used to express her opinion of its comforting powers. Certain it is that, within a week of her beginning to take it, she could stand upright, move her arm with tolerable ease, and give a moderate grasp with her hand. The hyoscyamus and camphor pills were discontinued after the second night, and substituted by ten grains of compound colocynth pill, on account of her troublesome constipation.

From the time of this improvement she had no morbid fancies or fears, and her appetite was better, though far from good, and the flatulence remained the same. Still the pain in the head continued, and the squinting; and the tongue was as flabby and furred as ever.

The treatment was pursued until the 18th of May, when, on account of her obstinate constiveness, we gave her ten grains each of scammony and jalap every morning in thick gruel—a good vehicle, let me tell you, for a nauseous medicine. The mixture continued as before.

On the 22nd there were no particular evidences of improvement over what had already taken place, and I determined upon trying the oxide of silver. At this time I felt more convinced than I had ever been, that tonic treatment was necessary—you will gather from the previous detail my reasons for so thinking—and, strychnine not having answered, I could find no better substitute than oxide of silver. I had often previously employed it in cases of nervous debility with benefit, and therefore felt no hesitation in giving it in this case. I administered it in the following form:—

R. Argenti oxydi, gr. iij.; extracti taraxaci pulv. rhei, aa. ʒss. Misce et divide in pil. xij. quarum capiat j. nocte maneque.

The ammonia mixture to be continued as before. From the time of the administration of the oxide of silver, the patient improved. We first saw the fur leave her tongue, and then heard her speak of the gastric flatulence diminishing. After a time, the pain in her head decreased, and coincidently with this was a diminution of the size of the pupil, and a return of the eyes to their natural axes. Strange as it may seem, and to myself as the narrator and observer it is not less strange than to you as student-observers, the eyes by degrees recovered their natural state and appearance, and, in ten days from the time of her beginning the oxide of silver, she not only could see distant objects clearly, but could read a small bible (as we heard her) without hesitating. At this time she walked about the ward without difficulty; her tongue was healthy-looking; her appetite good, digestion easy, and unaccompanied with flatulence; bowels regular without aperients; and instead of squinting at us, as she had previously done, she directed an intelligent pair of dark eyes at any one of us whom she particularly wished to notice. She also improved in general strength and substance.

From this period we had had no deviation or drawback from rapid recovery. Without noting the course of healthy progression, it is sufficient that I remind you of what yourselves saw—that the woman became convalescent as rapidly as

could be desired. The last time we saw her together she had no pain or numbness of any kind; she could read the smallest print with ease, and the axes of her eyes were parallel; her bowels were quite regular; appetite good, and digestion easy; no flatulency; tongue quite clean, and of a natural redness; the arm and leg that were previously paralyzed she used with perfect freedom; secretions healthy and uniform. In a few days she was dismissed well (June 8), and so she has continued to the present time.

As I told you at the beginning, this case was marked by its various anomalous and perplexing features. It has many equals in the strange histories with which medicine abounds, yet I have thought it curious enough to be made a matter of individual detail. As the sequel proves, there was nothing wrong in the brain which an improvement in the digestive organs did not rectify. The ammonia and the sulphuric ether certainly rendered her much benefit, but diffusive stimulants were not wholly sufficient. It was not until the oxide of silver was given that that suspicious-looking tongue improved and its accompanying flatulence subsided. I might occupy a great deal more time by speculating on the *modus operandi* of the materials that did this singular service, but I am not satisfied that I could theorize to any useful purpose: yourself, like your lecturer, must be satisfied with the fact. The woman recovered from a most anomalous state, and is now in the enjoyment of excellent health; perhaps this is the best comment, though it conveys no explanation.

I had an extraordinary case some time ago, in the person of a dispensary patient, excellently illustrative of gastro-intestinal influence over the cerebro-spinal system. It was a little boy, about eleven years old, who became the subject of strange convulsions, alternating sometimes with almost complete paralysis, and again with partial coma. This state of things had continued, in defiance of all remedies, for four or five months, when the boy became Mr. Carter's patient. About three months subsequently I was requested to see him. There were many appearances which seemed to indicate disease of the brain, but there were others that referred especially to disturbance of the stomach and bowels. For months the boy was unable to get beyond the door, and for weeks he was confined to his bed—at one time convulsed frightfully, and at another lying motionless and insensible for hours together. Leeching, blistering, mercurials, vermifuges, tonics, and stimulants were tried, but all without avail. We gave strychnine for some time, but it did no good. At last we gave the oxide of silver, in doses of half a grain, twice a day. He had not taken it three weeks when he became perfectly free from his fits, and capable of walking a short distance alone. One of you saw him with me the other day. At this time, rather more than two months since he began the oxide, he regularly comes to me at the dispensary, unattended, and has to walk upwards of a mile to give me the visit.

I have no commentary to offer upon this case, which, like many similar ones, is certainly produced a wonderful effect. I do not mention the case, however, to vaunt a single remedy, but to show you how close a relation holds between the digestive apparatus and the organs of sense and intelligence; and how these are often to be remedied by relieving the other.

A COURSE

OF

LECTURES ON SURGERY,

BY

SAMUEL COOPER, Esq., F.R.S.,

Professor of Surgery to University College, London;
Consulting Surgeon to London University Hospital, &c.

LECTURE XIII.

In the last lecture, gentlemen, we considered mortification as it arises from acute inflammation

—acute mortification, as it is sometimes called, though not correctly—mortification proceeding from acute inflammation. We now consider the chronic form of mortification, or dry gangrene. This is produced by different causes—such as advanced age, an impaired state of the general health, or disorder of the whole system; diseases of the valves of the heart, causing distention of the veins, especially those of the lower extremities; also, from other obstructions of the circulation, such as ossification of the large arteries, and obstruction of their smaller branches by fibrin; the ossification taking place often under unfavourable conditions of the general constitution.

The first example of chronic mortification, or dry gangrene, is the gangrena senilis, or mortification of old persons. This kind of mortification differs in many respects from any other example; it is peculiar in the discoloration which takes place, being always preceded by severe burning sensation in the parts. It commonly occurs in elderly persons—in nineteen cases out of twenty. Not that you may not have similar cases in the youth. Dupuytren relates several instances of young persons suffering from this disorder. It commences at the greatest distance from the centre of the circulation, generally on one of the toes, in the form of a dark purple spot at the side of one of the small toes. Previously, however, you find the patient has been suffering pain about the toe, which is often supposed to be gout; and you find that the extension of the disease is preceded by burning sensation. Its progress is variously marked in different cases: you find that the foot is gradually, sometimes quickly, affected as far as the ankle, and has a dark livid colour; the leg higher up presents a reddish-brown colour, and the whole limb has a mottled appearance. When the surgeon examines the part of the leg higher up, he finds the temperature of the limb much lower than natural, and this loss of heat is found to extend along the limb. Dupuytren thought that the temperature of the dead limb fell below that of the surrounding media—that of the atmosphere, and he believed his opinion was confirmed by experiments that he made with the thermometer. Although this is called dry gangrene, in most cases there is a separation of the cuticle, and a dark bloody serum effused into vesicles, as in acute mortification, and at the bottom of the vesicles is seen the cutis, dark coloured and livid. Whether you are to have much swelling depends on the rapidity with which the disease extends: when it advances rapidly there is much swelling, but where the progress is slow the swelling is generally very slight. I have mentioned that the progress is different in different cases: the patient sometimes suffers a great deal of disturbance in the stomach; he suffers from eructations, and delirium and coma come on early in severe cases. Where the disturbance is great in the beginning, the patient often dies before the mortification has reached to the ankle, about the tenth or twelfth day, from constitutional disturbance. I attended a case of this kind at Staines: a wealthy grazier who had indulged very much in eating and, I believe too, in drinking; at all events, he was a voracious eater; he was an example of death taking place about the tenth day: the disturbance being great, and coma and low delirium coming on early. His case was an example of very rapid mortification. I also attended another gentleman, in Gray's-inn, with Mr. Hughes, of Holborn. He had a small spot on one side of one of his little toes; he had no suspicion it was a disease of any consequence. I told him at once that it was a very serious disease, but he would hardly believe it. He had very little constitutional disturbance, though his pulse was quick, about 100 or 110; he slept well, and eat a chop daily; and it was not till his stomach began to fail that he could be brought to believe he was in an imminently dangerous condition. What helped to bring this patient to his latter end was the gangrena senilis attacking the other leg. In this case, every time there was spreading of the

mortification, such extension was preceded by intense burning pain in the part about to be destroyed. But the most remarkable fact in the case was, that the two legs were attacked differently. One limb became cold, and lost its sensibility; the other became flaccid and untumefied, as the French physicians say. This patient lived till the sixth week, but then sank rapidly. He was attended also by Sir Astley Cooper. Another case I attended was that of a lady residing in Guildford-street, who was attacked with gangrena senilis of a spot on the heel; so that you are not to suppose that it always begins in the toes, though this is very common. So slow was the progress of the disorder in her case, that she lived eleven months after its appearance, and when she died the gangrene had not reached higher than the ankle.

Now, what are the causes of gangrena senilis? It has been generally supposed that there is ossification of arterial trunks, and sometimes we can feel very distinctly that the artery is ossified; but in many of the cases I have seen it has not been so. The larger arteries are not invariably ossified in this disease; sometimes we have obstruction of the arterial trunks; obstruction of the smaller arteries is constantly found, but obstruction of the larger more rarely. Cruveilhier always referred gangrena senilis to ossification. There must be some unfavourable circumstances combined, with the ossification, as impaired health, diseases of the heart or its valves, producing disorder of the circulation. Then the venous blood cannot pass freely, and accumulates in the lower extremities, impeding the circulation; and this will explain to you the cause of gangrena senilis. It is doubted by many good surgeons whether ossification of the arteries alone is capable of producing gangrena senilis. I think it is not. No doubt in a broken constitution, joined with ossification, it may act as the exciting cause. Dupuytren thought the cause was arteritis, by which the arteries become blocked up by fibrin. It was observed that the blood was buffy, in consequence of his view, he tried venesection, and three-fourths of his patients were cured. This mode of treatment, when tried in this country, did not give such favourable results. There was one case treated by Gibson, a surgeon, of the United States, that was successful, but unfortunately, very soon after the patient was pronounced out of danger, he died suddenly, so that I do not know whether we have sufficient proof of the correctness of this practice. We found that bark was inefficient in this disease, and that opium was a much more available remedy; and the opinion is retained by the best surgeons, that opium is better than bark in the treatment of gangrena senilis. If opium or its preparations be used, half-grain doses of hydrochlorate of morphia should be given every four hours. There can be no doubt that opium is very useful in gangrena senilis; ammonia also has been used in most of the cases that I have seen; but, I must say, most of the cases I have seen have terminated unfavourably. Musk, too, has been tried, and was found to be a most useful medicine. Stimulants, brandy and wine, ought not to be forgotten. With respect to the local treatment, fomentations and emollient poultices are the most employed. I have seen other applications tried; I have seen Labarraque's solution of chloruret of soda, and this, in one case I attended, had the effect of diminishing the fetid smell, but did no other good. I remember that Sir Astley Cooper tried it, but, according to his experience, it had no other effect than that I have mentioned. Applications of charcoal were also tried, but these were no better than the other. A new practice of late has been introduced; in Chelsea Hospital, where gangrena senilis is very common among the pensioners, it was suggested that it would be a very rational plan to maintain the temperature of the limb by enveloping the whole in carded wool. This was tried in a case by Sir Benjamin Brodie; this patient got better, and recovered with the loss of two toes.

Now, you have examples of dry gangrene in various conditions of the general health: some-

times the constitution is so disordered that no function will go on well; and in particular the circulation and innervation are especially impaired. You find in that state of the system which takes place in scurvy, that gangrenous ulcerations, or aphthæ, occur on the mucous membrane of the mouth, and other mucous membranes. You may often find in this form of gangrene, in persons who have been under mercurial treatment for some time, where mercury has been used in cases of syphilis to an unwarrantable extent—pushed, as the term used to be—the linings of the cheeks will slough, and ulceration will take place. Persons, too, who have been confined long by typhoid or scarlet fever, are peculiarly liable to be attacked by this complaint; and, as analogous to this, I may call to your notice the mortification which takes place over the sacrum and scapula in persons who have been long confined to bed by diseases of the hip-joint, in the suppurative stage, or by bad fractures; these patients get into such a low condition, that from pressure the soft parts covering the bone become the seat of gangrene. The skin becomes brown, and sloughing comes on, but sometimes in such a degree that the muscles and fasciæ are involved, and the bones are exposed. Often, where the worst stage of compound fracture has been got through, I have seen this gangrene take place and carry the patients off. When you consider the causes of this kind of mortification you will see the difficulty of curing them, as it not only proceeds from pressure, but also from a low state of the constitution, and hence you may remove the pressure and yet not be able to stop the disease. Still you must endeavour to take away the pressure, and you may employ for this purpose pillows or air-cushions, placed under the patient so as to relieve the prominent parts, or, better still, hydrostatic bed—Mr. Arnott's water-bed—which acts upon the principle of equalizing the pressure. This water-bed sustains the lower surface of the body at every point, and diminishes the pressure on the prominent parts by affording a very soft surface for the patient to lie on. When long confinement has taken place, you must be on your guard: examine the parts of the skin; see that they are washed well with astringent lotions—the lead lotion, liquor plumbi, and also a preparation of camphor—camphorated spirit. By altering the position of the patient you may sometimes succeed in preventing this mortification. I have often applied the soap plaster—either white or brown—which is a very good application, though not so good as bathing frequently the part during the day with strong astringent lotion. When sloughing comes on, the modes of treatment are very different amongst different practitioners. Some poultice, some apply camphorated spirit, and some the liquor plumbi lotion; others a strong solution of the chloruret of soda. These are only secondary means in the treatment of this kind of mortification. When mortification occurs in consequence of external injury of an artery—as, for instance, in case of a musket-ball passing through the thigh, and wounding the femoral artery—in such cases the foot mortifies. The foot loses its temperature, and you amputate as high or higher than the wound in the artery.

Generally speaking, when the femoral artery is wounded the thigh will not mortify; but when the wound is inflicted by a gunshot, not only is the femoral artery injured, but also the veins and lateral muscles; and this is the reason that gangrene comes on. If the thigh be wounded by a penknife, mortification will not be likely to take place. Where there is mortification under these circumstances, the disturbance has been great, or the constitution is unfavourable, or the limb has not been under proper treatment; mortification may then be very great.

I mentioned venous obstruction as a cause of mortification. This, sometimes, will arise from the too great tension of the bandage; the bandage presses tightly on the veins, and hinders the return of the blood; effusion then takes place and the swelling increases; the bandage thus

becomes still tighter till mortification ensues. You must also take notice of another matter—which is the position of the limb; this must be placed favourably for promoting the return of the blood.

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART VIII.

PHOSPHORESCENCE OF LIVING BODIES.

Many living bodies possess the singular faculty to emit light. The best known case of animal phosphorescence is that of the glow-worm (*Lampyris italica*—*ver luisant*, *luciola*), a coleopterous insect of yellowish colour, living in meadows, and chiefly met with in spring and summer, after sunset.

The two last segments of the body of this insect appear slightly luminous in the dark, and emit at night, intermittently, a comparatively strong light.

The results of numerous experiments made with this insect by Macaire and others, but more particularly by the author, have led the latter to the following conclusions:—

1. The phosphorescence of the glow-worm is owing to the presence of a peculiar matter in this insect. The manifestation of the phenomenon is not indispensably connected with, or dependent upon, the life or absolute integrity of the animal.
2. In carbonic acid and hydrogen the phosphorescent matter of the glow-worm ceases to shine after the lapse of a certain time, not exceeding from thirty to forty minutes, if the gases are pure.

3. In oxygen gas the phosphorescent matter of the glow-worm (no matter whether the entire animal, or simply the luminous segments, be used in the experiment) shines with considerably greater brilliancy than in atmospheric air.

4. The phosphorescent matter of the glow-worm, when placed in conditions adapted to cause the emission of light from it, absorbs a portion of oxygen, and evolves an equal volume of carbonic acid.

5. The same substance, when deprived of the faculty of emitting light, absorbs no longer oxygen, nor evolves carbonic acid.

6. In a medium of pure oxygen the phosphorescent matter continues to shine for several days, after which it loses its luminousness; a portion only of the oxygen is found replaced by carbonic acid. In a medium composed of one part of oxygen to nine parts of hydrogen or carbonic acid, the phosphorescence continues for several hours. This would lead to the conclusion, that the cessation of the phosphorescence (in the former case) is owing simply to surviving decomposition of the phosphorescent matter.

7. Elevation of temperature, within certain limits (up to about 80° Centigrade), increases the intensity of the light emitted by the phosphorescent matter of the glow-worm. Depression of temperature has the opposite effect.

8. Exposure to a higher degree of heat (about 96° Centigrade) causes decomposition of the phosphorescent matter. Continued exposure to the air or any other gas, produces the same effect, after a longer or shorter period of time, according to the nature of the medium. It is indubitably for this reason that these insects do not live in all climates, and shine only during certain periods of the year.

9. Phosphorescent matter, thus altered or decomposed, is no longer apt to emit light, or to become luminous.

These conclusions demonstrate and establish evidently the nature of the phenomenon: the generation of the light in this insect is inseparably connected with the combination of oxygen with the carbon that forms one of the elements of the phosphorescent matter.

We have now to proceed to inquire in what manner the phosphorescence is produced in the living animal, and to examine the circumstance by which the phenomenon may be influenced, and

the structure of the luminous matter and of the surrounding parts.

The author placed several glow-worms in a close-shutting tin box; upon opening the box, twenty-four hours after, and about two hours after the setting of the sun, he found the glow-worms apparently dead, but still emitting a feeble light. The warmth of the hand restored to them, to some extent, the power of motion, and rendered the light somewhat more intense.

In another experiment the author kept several glow-worms for thirty hours in the same tin box: upon opening the box some of them were found dead, and without the slightest trace of luminousness; in others the luminousness was exceedingly feeble. The results of these experiments would tend to prove (supposing the whole of the preceding conclusions to be based on erroneous data) the correctness of the *insolation* theory, adopted by Becaria, Mayer, &c., as explaining the phosphorescence of these insects.

But the results of another experiment of the author's disprove this view and theory altogether and completely. The author placed a great number of glow-worms in one of the compartments of a double-bottomed, close-shutting tin box, and in the other compartment an equal number of these insects, scattered through a quantity of fresh grass that had been gathered in the same place where the insects were found. Upon opening the box, after twenty-four hours, the glow-worms in the former compartment were found dead, or nearly so, whereas those in the latter were found very lively and luminous, and continued so during the nine days that the author kept them in the box, supplying them from time to time with fresh grass. This experiment proves conclusively that the phosphorescence of glow-worms is not ascribable to insolation.

If you look at the last segments of the abdomen of a glow-worm, at the moment of the capture of the insect, you will find them of a glossy reddish colour. During daytime this colour is less distinct, and inclines to yellow, and the same is the case with dead glow-worms. Whilst the insect continues alive the segments are observed from time to time to turn luminous. Careful and attentive observation will show that the luminousness does not always appear upon all points of the segment, at once. A slight irritation of any part of the body of the insect suffices to cause a momentary appearance of luminousness, which persists somewhat longer when one of the points of the luminous segment is excited. If the head of the animal be cut off at this moment, the light will immediately fade, and subsequently entirely disappear, when the red colour of the membrane of the luminous segments may be distinctly seen. In this state the strongest irritation of the thorax of the insect will fail to induce luminousness; but upon touching the luminous segments themselves the irritated points will shine, and the light will thence spread all over the segments. This phenomenon may be observed more distinctly still under the microscope, provided the observer take care to avoid the approach of light to the subject: an exceedingly rapid oscillating movement is seen to take place in the particles of the phosphorescent matter, which at the same time turn luminous.

The author has made, also, several experiments with a view to ascertain what influence nux vomica and opium may exercise upon the phosphorescence of glow-worms. He prepared for this purpose solutions of 0.265 grammes of extract of opium, or of alcoholic extract of nux vomica, in 61 grammes of water. He placed the insects in a glass jar, which he filled subsequently with one of the other of these solutions, and inverted afterwards over similar liquids, avoiding thus contact with the air. The results of a great number of experiments led the author to conclude that glow-worms die eight or ten minutes sooner in a solution of nux vomica than they would in pure water; whilst in solution of opium, on the contrary, the phosphorescence continues eight or ten minutes longer than it would in water. To this may be added, that glow-worms that have

ceased to shine under water, recover their luminousness on coming in contact with the air; whereas those that have been subjected to the action of nux vomica or opium are positively dead, and entirely and for ever deprived of the phosphorescent faculty. This proves the action of certain substances upon the phosphorescence of glow-worms—an action which, in all probability, cannot consist in any alteration of the phosphorescent matter.

The author varnished the abdomen of a great number of glow-worms with turpentine: he found the luminousness decreasing in intensity, and the scintillations becoming less frequent, without, however, disappearing altogether in any case.

The luminous organ of the glow-worm has been examined under the microscope. After removing from the luminous segments the dorsal and abdominal membranes, the microscope shows a globular granular yellow matter, in the midst of which appear groups of red globules, a great many ramifications, and, besides these, a sort of tubes, which present the appearance of muscular fibre; upon closer inspection, however, they appear void. Inspection of the luminous segments in the dark shows that the light is emitted by the granular yellow matter; and when the latter is inspected compressed between two glass plates, the luminousness is invariably found on the border of the inspected portion.

The abdominal membrane, carefully freed by washing from all phosphorescent matter that may adhere to it, appears upon microscopic inspection transparent, and covered with a great number of hairs. The dorsal membrane is less transparent, and likewise covered with hair, and presents, moreover, at its internal surface a great many tubes, which are seen to penetrate into the phosphorescent matter. Beneath the last but one luminous ring of the abdomen is invariably found a vesicle of a fine red colour, which, inspected under the microscope, appears to consist of a group of red globules. This vesicle is never met with in other insects, nor is it mentioned in any work on comparative anatomy.

We have to add a few words respecting the chemical action of the phosphorescent matter. This substance, taken from the living animal, has a peculiar odour, resembling that of the sweat of the feet; it is neither acid nor alkaline, dries readily in the air, and seems to coagulate in contact with dilute acids; neither alcohol nor ether, nor weak alkaline solutions, dissolve it to any appreciable extent, but it is dissolved and decomposed by concentrated sulphuric and hydrochloric acids, aided by heat; the fact that the application of the latter agent does not turn the solution blue, proves the absence of albumen. When heated in a tube, it disengages the usual ammoniacal products. The author did not detect appreciable traces of phosphorus in it; if a very large number of glow-worms were operated upon, the slight trace of phosphorus which is usually found in all organized substances might, perhaps, be detected in the phosphorescent matter of this insect; but, after all that has been stated here, the presence of phosphorus cannot be considered the cause of the luminousness of the animal.

It has been stated already that all the experiments made with glow-worms tend to show that the contact of the phosphorescent matter with oxygen gives rise to the emission of light, attended with absorption of this gas, and evolution of an equal volume of carbonic acid; and that these phenomena cease the moment that the phosphorescent matter has lost its luminousness.

We may suppose, therefore, that contact of the atmospheric air, or rather of its oxygen, with a peculiar substance principally composed of carbon, hydrogen, oxygen, and nitrogen, takes place in the numerous tubes found to exist in the luminous segments of the glow-worm. The great number of red globules found scattered through the granular luminous mass proves these segments to be the centre of a particular organ of secretion. Instances of spontaneous combustion of organic substances

are by no means novel: we need simply point out here the case of decaying wood, charcoal, in its state of minute division, &c. That the chemical combination of the oxygen and carbon, to which we ascribe here the emission of light by the glow-worm, is unattended with the usual evolution of heat, admits readily of explanation. The amount of carbonic acid disengaged within a given time from the luminous segments of the glow-worm is so minute that the heat evolved by the process of combustion cannot accumulate in them; the phosphorescence of decaying wood, and many more similar facts of emission of light attendant upon chemical modification, prove to evidence that emission of light need not necessarily be attended with any appreciable augmentation of temperature. Our instruments indicate only the presence of accumulated heat; and this accounts also for the apparent absence of heat in animals with cold blood.

In conclusion, we will briefly allude to some other known instances of animal phosphorescence.

It is well known that long tracks of light are frequently observed at night on the waters of the ocean; this phenomenon was formerly attributed to the meeting of the waves, to electricity, or to the presence of phosphorous gases formed by the putrefaction of mollusca; but it seems really to be owing simply to the presence of phosphorescent microscopic animalcules. But we are altogether in the dark respecting the physico-chemical conditions under the influence of which these infusory animalcules acquire phosphorescence.

It is an unquestionable fact that dead fishes emit light; the phosphorescence of the sea may in some cases be owing likewise to this cause. This phosphorescence of fishes ceases *in vacuo* and in carbonic acid, but reappears in the air. The annals of medicine mention several well-authenticated facts of flames perceived on the bodies of certain patients, and also of phosphorescent perspiration of the feet; with regard to the latter, it is extremely curious that there should exist an analogy between the odour of the phosphorescent matter of the glow-worm and that of the perspiration of the feet. We are as yet unable to account for any of these instances of phosphorescence.

Botanists tell us that in several plants inflorescence is accompanied by phosphorescence; but this phenomenon likewise is of too rare occurrence to admit of being conveniently studied.

Quatrefage has recently made some experiments on the phosphorescence of the *annelides* and *ophiuri*. Microscopic inspection revealed to this distinguished observer that the phosphorescence of these animals is seated in the muscular fibre, is intermittent, becomes more intense upon irritation of the fibre, ceases there upon for a time, and reappears subsequently again after the animal has been permitted to rest.

The results of these experiments of Quatrefage (which it would be extremely desirable to see confirmed and still further extended) offer to us a point of analogy which should not be lost sight of. The life of the muscles, and their functions, are attended with disengagement of heat and of light, and yet this life and these functions are immediately dependent upon the agency of the nervous system.

PART IX.

ELECTRIC CURRENT OF THE MUSCLES.

The joint contact of two different parts of a muscular mass of a living or recently killed animal with a conductor gives rise to the production of an electric current. This fact may be conclusively demonstrated by a very simple experiment. Take a frog, and prepare it after the usual method of Galvani; cut the pelvis through the middle, separate carefully the muscular part of the thigh, and cut off one of the lumbar plexus at its issue from the vertebral column; this will give you a frog's leg united to its long nervous filament, composed of the lumbar plexus and its extension to the thigh, viz., the crural nerve.

A leg thus prepared, and which may not

improperly be called *galvanoscopic*, is of very great use in experiments on the electric current. For this purpose it suffices to introduce the leg into a glass tube, covered with an insulating varnish, to seize the tube, and to bring any two points of the body under examination into contact respectively with two different points (sufficiently distant from one another) of the narrow filament of the galvanoscopic frog's leg. If every care be taken to avoid the slightest contact of the body under examination with any portion of the muscular part of the leg, and if the latter be strictly isolated from the hand, the contractions exhibited by the galvanoscopic leg must be attributed unquestionably to an electric current generated in the body under examination, and which the nerve simply conducts and renders perceptible by the contraction of its muscle.

Now, take any living animal, a pigeon for instance; make a slight incision in the pectoral muscle, after having carefully removed the integuments, and insert into the wound the nerve of the galvanoscopic frog: the leg will immediately contract. If we reflect upon the disposition of the galvanoscopic frog, we cannot avoid arriving at the conclusion that it is absolutely indispensable to bring two different points of the nervous filament respectively into contact with two distinct parts of the pectoral muscle of the pigeon. If the extremity of the nerve of the frog is made to touch the bottom of the wound, whilst another point is placed in contact with the lips of the wound, or with the external surface of the muscle, the galvanoscopic leg exhibits constant contractions; this demonstrates conclusively the presence of an electric current circulating in the nerve.

That the blood has no share in the production of the phenomenon may be readily proved by a simple experiment. Put a drop of the blood of the same pigeon upon a glass plate, and place two distinct points of this drop in communication with the nerve of the galvanoscopic frog: no contraction will ensue.

Moistening either the nerve of the frog or the living parts of the muscle of the pigeon with a saline or acid, or, better still, alkaline solution, renders the contractions more vigorous. These solutions act chemically upon the substance of the nerve or muscle.

The muscles of all animals, no matter whether with warm or cold blood, manifest the same phenomenon, and this even when the nerve of the galvanoscopic frog is placed in contact with a muscle severed from the body.

The contractions excited in the galvanoscopic frog suffice to indicate the existence of an electric current, which we will call "*muscular*," and which is generated in the muscles of a living or recently-killed animal, and, proceeding thence, insulates in the nerve of the frog. But we must have recourse to the galvanometer to place the existence of this current beyond doubt or question, and to discover the laws which govern the phenomenon.

If an incision be made in the pectoral muscle of a pigeon (from which the integuments have been previously removed), and the extremities

the platinum wire of a highly susceptible galvanometer be rapidly brought into contact—the one with the external surface of the muscle, the other with the interior of the wound—the galvanometer will immediately mark a deviation of 5, 20, and more degrees, and thus demonstrate the existence of an electric current in the muscle, proceeding from the internal part of the muscle to the surface; the index will speedily drop again, and, in many instances, return at once to 0. If the extremities of the platinum wire be now removed from the interior of the wound, and the experiment be then renewed, a new but somewhat less marked deviation will be observed. In some cases, however, the deviation in the second experiment proceeds in an inverse direction with respect to that observed in the first. The results of the experiment are consequently not sufficiently conclusive, and do not rigorously demonstrate the existence of an electric current in the muscle. There is evidently

some imperfection in this method of operating which a skilful experimentalist will readily detect and endeavour to remedy. The author recommends on this subject his work entitled "Treatise on the Electro-Physiological Phenomena of Animals."

The author has, however, succeeded to establish conclusively the existence of the electric current in muscles, and to discover the fundamental laws of this phenomenon.

The author took five or six frogs, prepared after the method of Galvani, cut them into halves, and severed the legs from the body by disarticulation; he finally divided the legs transversely into two parts, and selected for the subsequent experiment the lower parts. The experiment was conducted on a varnished table containing several capsular holes. The author disposed one of the parts in a manner to place its external surface into one of the capsular holes; to this he joined a second, touching with its external the internal surface of the first; to the same part he joined a third in the same way, and so on to the last part, which again was placed with its internal surface in another of the capsular cavities of the table. The whole formed thus a pile of half legs of frogs, of which the external surface of the muscle formed the one, and the internal surface the other, extremity. The two cavities were filled with slightly saline or with distilled water, and the two extremities of a galvanometer were respectively immersed in them: an immediate deviation of the index demonstrated the presence of an electric current produced by the muscular pile. The same result was obtained with the muscles of other animals. The intensity of the current is in direct ratio to the number of muscular elements used to form the pile.

The author examined also the other tissues and organs of animals, such as membranes, nerves, the brain, the liver, the lungs, with a view to ascertain whether they possessed likewise the faculty of generating an electric current: he found invariably that the galvanometer was but very slightly affected by piles formed of these organs or tissues.

The author has convinced himself by numerous experiments that the generation of the electric current in the muscles is independent of the nervous system.

If the galvanometric experiments are repeated several times with the same muscular pile, the deviations grow gradually less and less marked, and cease ultimately altogether, and this the more speedily the higher the animal stands in the scale of being.

The author managed to repeat his experiments with the muscles of living animals, and obtained invariably the same results. With live pigeons he found the electric current stronger at the commencement than with live frogs; but he observed likewise that the current ceased more speedily with the former than with the latter.

Comparing the results obtained with muscles of animals that have been deprived of food, or in which the blood circulates slowly, or in which the sanguine circulation has been altogether stopped, with those obtained with muscles of well-fed animals, or muscles gorged with blood, the author found the current in the former less, in the latter more, intense and persistent than is the case with muscles taken from average animals.

Poisoning with narcotics, carbonic acid, hydrocyanic acid, arsenuretted hydrogen, does not impair the intensity of the muscular current; but poisoning with sulphuretted hydrogen deprives animals nearly altogether of the faculty to manifest the existence of this current.

The current produced by a certain number of muscular elements is of equal intensity and duration, whether these elements be placed in more or less rarefied air, in oxygen, hydrogen, or carbonic acid.

The results of the experiments made by the author fully demonstrate the existence of the muscular electric current, and establish the laws of the phenomenon. The origin of this current resides in the electric conditions produced by the

chemical processes of the nutrition of the muscle. The blood charged with oxygen, and the muscular fibre which undergoes transformation in contact with this liquid, form the elements of a pile; they may be looked upon as the acid liquid and the metal. In the normal state of the muscle there can exist only molecular currents produced by the formation and destruction of opposite electrical conditions at the same points; but when a great number of points of the muscular fibre are placed in communication, by means of a good conductor, with other points of different nature, and not subjected to the same chemical action of the blood, the electric current circulates through the muscular mass. This fact, which has been fully established by experience, proves, on the one hand, the development of electricity in the living muscle, and shows, on the other hand, that this current cannot possibly exist in the mass of this muscle in the natural and normal state.

ORIGINAL CONTRIBUTIONS.

REPORTS ON THE DISEASES OF FEMALES.

By EDWARD RIGBY, M.D.,

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London &c.

ON STERILITY.

I propose to offer some observations on a condition in the human female which naturally excites much interest, and which, from the variety of forms it appears under, of causes it depends upon, and of treatment it requires, presents a field of investigation perhaps second to none in importance, in the difficulties of its diagnosis and treatment, and in the striking results when that treatment is attended with success.

I think we shall simplify the subject of sterility by bringing it under the two heads of *organic* and *functional*—the one in which the incapacity to conceive depends on injury or structural defect; the other on obstructed or suspended function from local or general derangement.

Under the first head come those congenital defects where more or less of the generative organs are either deficient or wanting, or at least, if not entirely wanting, in so imperfect a state as to deserve the term "rudimentary"—a form of sterility which necessarily offers but little hope of affording relief; to this place also belong contraction and occlusion of the os uteri, of the canal of the cervix, the vagina, and os externum, in all their varieties; polypos and other uterine tumours, whether malignant or not; organic disease of the ovaries and Fallopian tubes.

Under the second, which I propose to denominate the functional form of sterility, we must class inflammation of the ovaries, inflammation of the cervix uteri; inflammation, ulceration, &c., of the os uteri; displacement of the uterus; rheumatic or gouty affection of that organ; menorrhagia, leucorrhœa, and general debility of the whole system, whether causing, caused by, or unconnected with any of the affections just enumerated.

This form of sterility, which depends on functional derangement, displacement, or debility, presents a much more encouraging field for investigation, and also for removing those causes of ill health and suffering which are so intractable and obstinate under ordinary treatment. Fortunately the forms of sterility which arise from organic defect, and therefore come under the first head, are not of frequent occurrence. Of these I have already reported some cases under the heads of Amenorrhœa and Obstructive Dysmenorrhœa: (a) of the former many are quite incurable; whereas of the latter many admit of much relief, and even sometimes complete cure.

(a) *Medical Times.*

In offering these observations on sterility I presume that it is not necessary to refer merely to cases among married women who have not become mothers; but that I may adduce cases of unmarried females where causes of sterility have existed, and which I have endeavoured to remove by treatment; by doing so I shall be able to illustrate my subject more fully. The first case is one of this sort; it is a case of amenorrhœa, apparently depending on imperfect development of the uterus, but where, by treatment, a certain amount of relief has been obtained. Properly speaking, it should have been reported under the head of Amenorrhœa, but, this not having been done, I have the less hesitation in presenting it under the present head, as I trust that its details will be found interesting.

M. S., aged twenty, unmarried, of anæmic and chlorotic appearance; constant headache; tongue pale, indented, with red papillæ; pulse weak; is subject to frequent attacks of epilepsy.

October 19, 1846.—Had never menstruated until three months ago, when she was under my treatment at St. Bartholomew's. I succeeded in bringing on the discharge by the internal use of ergot and borax, aloetic enemata, and sinapisms to the mamma, while, at the same time, a slight application of argenti nitras was made to the cavity of the uterus, and galvanism directed through the pelvis. By this combined treatment a tolerable discharge of catamenia was effected, with considerable improvement in her general health, and diminution in the frequency and severity of the epileptic fits. These, however, have continued to recur from time to time, especially just before the subsequent catamenial periods.

Was admitted into the hospital for women shortly before an expected catamenial period.

Examination per vaginam.—Cervix small and taper, soft and flabby; os uteri minute; the uterine sound passed with some difficulty, but showed a uterus of the natural length; it felt light and thin as regards its parietes.

R. Soda biberatis, ℥j.; secalis cornuti, ℥ij.; mistura acacia, ℥ij.; aquæ cinnamon, ℥ij.; sumat demid. statim et repet. post horas duas.

Nov. 4.—Expects to be unwell next week. Lallemand's instrument for applying caustic to the urethra was passed through the canal of the cervix into the uterine cavity, and the inner surface touched with nitrate of silver. Rep. med.

Nov. 10. The catamenia have appeared to-day copiously, and without pain; the epileptic fits are less severe in number and severity. Rep.

Nov. 13.—Has not had a fit for six days, which is the longest interval between the fits for a very considerable period. She has had several warnings of a coming fit, but none has occurred. Pulse better. Rep.

Nov. 20.—Has had one fit on the 18th, and two yesterday, but they are slighter than usual. Bowels offensive.

R. Pil. hydrarg. c. coloc., gr. x., alterius noctibus. Haustus rhæi c. magnes., ℥jss. om. mane. Rep. alia.

Nov. 24.—Appetito good; tongue pale and furred, with red papillæ, tremulous, much indented; bad taste in the mouth; no fit since last report. Repet.

Nov. 27.—Had a severe fit last night, preceded by the sensation peculiar to these fits. Pr.

Dec. 3.—Has had only one fit since last report. The menstrual period ought to arrive the 9th. Pr.

Dec. 8.—Fits less in number and intensity. Sound passed up with some little difficulty as usual. Argenti nitras was applied to the cavity of the uterus.

Rep. sinapismus enema et haust. secalis cornuti c. sodæ bichlorate.

Dec. 11.—The catamenial discharge appeared on the 9th, and still continues; it is of a tolerably bright colour, and is better in point of quantity. The fits have been much less in number and intensity; headache better. Rep.

Dec. 22.—Fits much slighter, but still frequent; bowels open; tongue clean. Rep.

Dec. 29.—Fits have been more severe since last report; she expects the catamenia on the 9th of January, 1847. Rep.

Jan. 8, 1847.—The fits during the last week have been more severe, and of longer duration she expects to be unwell to-morrow.

Argenti nitras was applied to the uterine cavity, and the same emmenagogue treatment used as on former occasions.

Jan. 12.—The discharge appeared on the 10th, more profuse and of a better colour than before. She had three fits yesterday, but they were very slight, merely amounting to temporary unconsciousness. Bowels open two or three times a day.

Rep. mist. ferri citratis and pil. rhæi co.

Jan. 15.—No fits since last report; feels much better; tongue more natural.

Jan. 19.—Had a severe fit on the 17th; tongue pale; pulse feeble.

R. Argenti nitrat., gr. $\frac{1}{2}$; extr. hyose., gr. iv. bis quotidie.

R. Acidi nitrici dil., m. xv.; syngipi rhædos, 3j. ex aquâ destillatâ cum singulis pilulis.

Jan. 22.—Fits not so violent, but more numerous (three a day). Pr.

Jan. 26.—Has just recovered from a slight fit; catamenia appeared at the half-way time (on the 22nd); discharge was more profuse than it has yet been, it was attended with no pain; bowels open.

Omitt. pil. argenti nitr. Rep. pil. camphoræ c. hyose.

Feb. 2.—Much improved in health; only one fit during the last fortnight.

Rep. pil. argenti nitr.

Feb. 5.—Has had three bad fits since last report.

March 19.—Catamenia appeared on the 4th five days sooner than was expected; they came without pain, natural in colour and in quantity. Has been taking for some time half a grain of zinc sulph. three times a day with great benefit; has had only one fit since, and that very slight. Rep. pil.

March 26.—Has had eight fits since last report. Rep. med.

Let a sponge moistened with sulphuric ether be applied to the nostrils at the approach of a fit.

March 30.—Has had several fits since last report. On the 27th, sponge dipped in ether was applied to the mouth and nostrils on the threatening of a fit; had several precursory symptoms of a fit, which disappeared on the application of the ether. Rep. medic. and ether.

April 6.—Has had one severe fit since last report. The ether has been administered at the approach of several, which have been kept off. Rep.

April 13.—Has had two slight fits, which came on before the ether could be used; another was threatened, but it was prevented by the ether, although considerable drowsiness followed, as after a fit. Rep.

April 26.—Has had two fits since, one of which occurred under the influence of the ether.

This interesting case presents a variety of points well worthy of observation. It would be difficult to decide between cause and effect in the symptoms which have been enumerated; they may be summed up under three heads—*anæmia*, *amenorrhœa*, and *epilepsy*. The first is evidently capable of producing the two latter; but I pre-

sume it just to consider that the *amenorrhœa* might have tended in no slight degree to have kept up the disposition to *anæmia* and *epilepsy*.

I had endeavoured to correct this state by alteratives and tonics when she was at St. Bartholomew's, and then proceeded to make a vigorous effort for the purpose of rousing the uterine system. Besides the treatment which I have before recommended under such circumstances, I adopted a plan of rousing the uterus to a menstrual effort, which my friend Professor Simpson recommended to me, viz., of passing a piece of lunar caustic into the cavity of the uterus by means of an instrument similar to that which has been used by Lallemand for the urethra, and painting its inner surface with it; this acts as a considerable stimulant to the uterus, and, if the powers are equal to the task, a secretion of catamenia generally follows in the course of twelve or twenty-four hours after. In the present case this succeeded with the assistance of a variety of other measures, which, when combined, produce a powerful effect upon the uterine system, and evident relief followed; by a repetition of these measures, after a proper interval, the uterus gradually acquired the habit of making a periodical effort to secrete the catamenia, which became free and even copious in quantity. I tried my best to improve the general powers of the system by tonics, good food, and rigid attention to the state of the digestive organs; but the pulse continued feeble, the face pale, the tongue flabby and indented at the edges; some of the more powerful tonics, as nitrate of silver and sulphate of zinc, which are considered to act very beneficially in epilepsy of the low *anæmic* character, were tried, and a certain amount of relief was produced; but, on looking over the history of the case, I cannot help coming to the opinion that mild sedatives allayed the epileptic seizures more than any other medicines which were exhibited, and I much regret that they had not been decided trial. The ether appeared decidedly beneficial at first, and appeared to ward off the fits very effectually at the onset, whenever the warning of their approach was sufficiently long it appeared, however, gradually to lose its effects, and she went into the country with considerable benefit to her general health.

GLYCERINE.

By J. STARTIN, Esq., Surgeon to the London Cutaneous Institution.

In reply to several correspondents in the pages of your Journal, and also to numerous letters personally received on the subject, I venture to offer a short account of the liquid substance termed GLYCERINE, or the sweet principle of oils; I have applied this substance in many cutaneous disorders, with a degree of benefit to the sufferers that renders a brief recital of its nature and properties and modes of application subjects of professional interest.

Glycerine was discovered by Scheele, and has since been chemically studied by MM. Chevreul and Pelouze, but was never applied therapeutically (as I believe) until by myself. This liquid exists naturally in the fats of animals and in fat oils, and has latterly been found by M. Goblet in the yolk of egg combined with phosphoric acid; its formula is $C_8 H_6$ (Liebig).

The original discovery of glycerine by Scheele occurred in the saponification of olive oil by oxide of lead—that is to say, in the preparations of lead, or *diacolon plaster*; it is also formed in the manufacture of soap, and by the makers of stearine for candles; but, in whichever case it may be developed, water must be present to dissolve the glycerine, which becomes liberated by the combination of the fat body with the metallic oxide, the alkali, or the lime, used in the manufacture.

When perfectly pure and anhydrous, glycerine is a nearly colourless liquid, of a sweet taste and syrupy consistence; it has a faint but not disagreeable odour, and possesses a great affinity for water, with which it readily com-

bines; it also easily unites with oils, and dissolves many gums and resinous substances; it will neither crystallize nor ferment like a sugar, (a) nor will it evaporate beyond a certain point, but is destroyed by ebullition. It is combustible, as may be judged from its formula, and burns with flame; and has been considered of the nature of an alcohol, forming with the acids combinations resembling the ethers in many respects; like alcohol, also, glycerine is a good antiseptic, and may be used alone for this purpose, or in combination.

Glycerine may be obtained very pure by saponifying olive oil or any fat matter, animal or vegetable, by litharge or oxide of lead, water being present during the chemical combination; all the ingredients are to be boiled together, care being taken to replace, by boiling water, any portion which evaporates. When the reaction is completed, glycerine will be found dissolved in the water which remains; but, as a portion of lead will also be contained in this solution, it will be necessary to pass a current of sulphuretted hydrogen gas through it, until the metal is precipitated. The liquor is next to be subjected to ebullition, to drive off the sulphuretted hydrogen, when it may be decanted, filtered through fresh-washed animal charcoal, and concentrated by evaporation first in a sand-bath, and finally in the receiver of the air-pump, when it will be found to possess the properties and appearances before described.

It was during the autumn of 1845, in a course of lectures on diseases of the skin delivered at the London Cutaneous Institution, that I first drew the attention of the medical profession to the use of glycerine as a therapeutic agent, and you did me the honour to publish my observations in the *Medical Times*. It was at that time seldom, if ever, preserved in the manufactories from which it is now obtained, and was then collected for me during the making of lead plaister at Apothecaries' Hall, by my friend Mr. Warrington, their able chemical manipulator; it could there be purchased by the pound for a few pence; but as its consumption has increased, and the production of the article in the manufacture alluded to is limited, the price has risen to 3s. 6d. or even to 7s. the pound, if the perfectly anhydrous article be desired. I now procure glycerine from Mr. Button, of Holborn-bars, who has taken much pains to procure it pure and concentrated at a moderate price. It is to be had, however, from Allen and Co., or any other first-rate chemists. The antiseptic and unclotting properties of glycerine first led me to attempt its use for medical purposes, as I believed, by the means of such properties, lotions, poultices, baths, &c., might be rendered peculiarly emollient and soothing. When preternatural dryness, roughness, or harshness of the skin was present, and particularly in those cases where the hair or scalp was involved, as in instances of dandruff or pityriasis of these parts, my expectations were more than realized by reducing my conjectures to practice; and I found that by the addition of one-fourth to one-eighth or even one-tenth of glycerine to any lotion, poultice, or external application, all the indications I have mentioned were fulfilled, and that such applications never became perfectly hard and dry, whilst soothing and tranquillized the diseased part, attracting moisture from the air, and thus keeping up a constant evaporation from the surface; its antiseptic properties also, in a great degree, prevented the unpleasant odour of vitiated secretions or discharges, whilst its undrying nature did not permit the formation of hard scabs or incrustations, which it is known very often interfere with the healing process, and occasion much pain on their removal. I have had little experience in the use of glycerine internally, but it is a mild stimulant, antiseptic and

(a) It is this property which has occasioned the employment of glycerine as a means for adulterating tobacco, which, I imagine, was carried to some extent when the price of the article would permit.

PRODUCTIVE INDUSTRY.—Since the introduction of European manufactures, Syria has suffered considerably: for the local manufacturers of silk and cotton stuffs of several descriptions, which formerly existed on a large scale in the cities of Aleppo and Damascus, have been ruined, because they cannot compete with the manufacturers of Europe, who, with the power and rapidity afforded by steam, can achieve far greater improvements, and sell them at a cheaper rate, to the injury of the Syrian manufacturer and capitalist.

The produce of Syria has little or no local demand, and, as regards foreign consumption, even less: for the prices given in the foreign markets are not adequate to remunerate the Syrian tradesman, agriculturist, or manufacturer.

The treaty of commerce between the European states and the Ottoman Porte of 1838 has greatly affected the internal trade, and also discouraged the agriculturist, for it imposes 12 per cent. upon the value of Syrian produce and industry, which duties are not only in themselves exorbitant; but form the main impediment to the merchants to export these produces, unless they should render themselves liable to a loss nearly proportionable to the amount of the duties in question.

By a late proclamation of the Turkish Government, the circulation of all old gold and silver coin is forbidden, and they have issued a new currency of gold and silver which—unlike the former one, that contained their intrinsic value in gold and silver respectively—bears a loss of about 25 per cent. on the gold gazee of twenty piastres (3s. 9d.), and about 55 per cent. on the silver ones.

The commerce of Beirut has increased within the last two years so considerably as almost to have doubled itself.

Custom-house duties on exports and imports are regulated by the tariff annexed to the commercial treaties between the European powers and the Ottoman Porte, viz.:—

Twelve per cent. on exports or produce, growth and manufacture of the Ottoman dominions, of whatever nature or description, which dues are paid on two occasions:—1. Nine per cent. on the purchase; 2. Three per cent. on the exportation of the goods to a foreign country, or its sale or consumption in any place in the Turkish dominions.

Five per cent. on imports, or the goods, &c., produce of a foreign country, which dues are paid equally on two occasions:—1. Three per cent. on the importation of the goods into any port of the Ottoman dominions; and 2. Two per cent. on the sale of the same, or removal to the interior.

These duties are paid in common by the subjects of the Porte, as well as by Europeans, except the Russian merchants, who only pay three per cent. on exports and imports; but the Turkish Government, by compelling their subjects to pay the inland duties (called also commutation duties), when they sell their produce to a Russian merchant, has put the latter nearly on an equal footing with the other nations.

All goods or commodities of every nature or description whatever are allowed to be exported and imported from and to the Turkish dominions, except powder and military arms, which are prohibited by the treaties.

The imports into Syria—and I now speak of the port of Beirut in particular—are as follows:—

From England.—London and Liverpool.—The cargoes consist of shawls, manufactured cotton goods, as printed cottons, &c., prints, muslins of several descriptions, both plain and figured. Those from London consist mostly of colonial produce, viz., indigo, cochineal, coffee, iron, sugar, cinnamon, pepper, pimento, tin in boxes and bars, ammoniac, earthenware, and iron and steel manufactured goods.

From France, or the port of Marseilles, several descriptions of grape, velvet, silk, cloths, red-caps, and colonials of all kinds, the same as those from England.

From Switzerland, several kinds of manufactured cotton and silk.

Trieste supplies cloths, caps, steel, earthenware, glassware, silk stuffs.

Leghorn sends caps, taffetas and other silk, yarn, and cotton manufactured goods, the same as those imported from England.

Egypt exports to Syria rice, wheat, barley, and other grain, skins, striped silks, small carpets, soap, copper wares, writing-paper, and linen goods of native manufacture.

The prices of corn and grain vary according to the recolt of Syria: for instance, if the recolt in Syria is favourable, the prices as well as the importation, of course, are moderate; otherwise, the importation is considerable and the prices high.

Since the late war in 1840, the country of Syria has suffered, more or less, from the want of corn, the produce of its own soil, in consequence of the Egyptian Government having taken all the young men for the militia, and Syria is now obliged to import corn from Egypt. Again, under the Turkish Government, the plains of Syria are no more cultivated as formerly, because they are not secure from the depredations of the different Arab tribes, as they were under the former Government, and, therefore, the demand for foreign corn has increased lately, and is, of course, very prejudicial to Syria.

Syria affords a great variety of wines, which are mostly prepared by boiling immediately after their expression from the grape. The chief of them is the *vino d'oro*, or golden wine, of Mount Lebanon; but the quantity produced is small. It is, as the name implies, of a bright golden colour, and bears a high price. "This wine is not boiled, but left to purify itself by keeping." (a)

The Exports.—Lebanon and its neighbouring plains produce silk, which is generally divided into three qualities, viz., *superior, middling, and inferior*, the prices of which vary from 50 to 105 piastres (b) for an oke (c) of 100 drachms; and oil, which costs from 800 to 900 piastres the cantar (d) (ewt.) of 200 okes, according to the quality.

The south of Syria exports cotton at 750 to 800 piastres the cantar; oil, wax, sesam, butter, grain of all kinds, and tobacco and soap. These produces have lately been so inconsiderable, on account of the discouragement of agriculture (which is depressed in some parts by arbitrary exactions, and in others by the ravages of the Arabs, against which the Government will not afford protection), that they hardly suffice for local consumption, with the exception of cotton and tobacco, which are destined for exportation.

Several varieties of gums, galls, skins, copper, wool, opium, and cotton, are exported to France, Italy, and England, from Aleppo, through the ports of Tarsus, Alexandretta, and Latakia. The gums, galls, and skins, are received from Bagdad; the remainder are mostly the produce of Carmania and Mesopotamia.

CLINICAL NOTES.

No. VI.

By RICHARD DE GUMBLETON DAUNT, Esq., M.D. (Edin.), Member of the Faculty of Physicians of Rio Janeiro; and Member of, and late Honorary Secretary to the Parisian Medical Society.

"Vous avez vu, c'est bien; vous avez fait, c'est mieux encore; mais qu'avez-vous vu, qu'avez-vous fait? Comment avez-vous vu, comment avez-vous fait? * * * C'est là le point essentiel, le temps ne fait rien à l'affaire, ni votre réputation, ni le nombre de malades que vous avez traités, bien moins encore l'âge que vous avez atteint. Quarante ans de pratique n'ont pas fait pénétrer dans votre dure et étroit encéphale une étincelle de génie scientifique; où l'intelligence est l'étoffe dont se fait le vrai médecin. Qui ne connaît l'histoire du mulet du Maréchal de Saxe?"

(a) "Browne's Travels," p. 432.

(b) One hundred and eight piastres are equal to one pound sterling, according to the present rate of exchange.

(c) Forty okes are equal to 100 lb. Troy weight.

(d) The cantar of the south of Syria consists of 200 okes, or 500 lb. Troy weight; that of the markets of Aleppo and Damascus is only 180 okes.

Ce pauvre animal avait fait la guerre pendant vingt ans; il avait vu, il avait fait une infinité de choses et cependant il était resté muet comme devant."—PARIS-REVUE.

The "tactus medicus," or medical instinct—on which was based the wide-spread reputation of nearly all the older celebrities of our profession, and which was pre-eminently possessed by the great Valentine von Hildenbrand and by the English Sydenham—appears a much rarer endowment of physicians in our own days; as if what had been gained in progress by the whole profession had, as in other branches of human studies and in moral qualities, been accompanied by the impossibility of the existence of those men, who to the students of those earlier periods are as heroes, and revered with meet hero-worship. The two instances cited are among those of its latest appearance, and perhaps no result of its possession has remained to us more worthy of repeated comment and study than the divination by Sydenham of the great law of epidemic medical constitutions of the atmosphere, which, in his own words, do not arise from visible atmospheric variations, "sed ab occultâ potius et inexplicabili quadam alteratione in ipsis terre visceribus pendet." With respect to febrile diseases, on which Sydenham dwelt for proofs of the truths of this law, and to which he appears to have restricted it, most practitioners of good attainments, and who profess orthodox doctrines, assent to its theoretical truths, though it is not so much studied in its practical applications as it ought to be. With respect, however, to the class of diseases called intercurrent, or which appear from chance causes, and are not epidemic, as, *ex. gr.*, the phlegmasia, its application is admitted by but few; and it is on this account that I now publish the afterwards-cited facts in confirmation. It was my good fortune to study for a time in the University of Vienna, where, the traditions of the teaching of the old masters, the glories of past centuries, whose innate sagacity well supplied the place of much of our present vaunted positivism of acquaintance with the local alterations of disease, still are cherished; and where, the spirit of the philosophy of the older medicine yet imparts an influence to the whole body of doctrine of the school. Here, and in the same language in which Sydenham wrote, I heard from the eloquent lips of Toltengi, the Professor of General Pathology, the most masterly enunciation of this great law, and, at the same time, an exposition of other not less important pathological laws, which, elsewhere, at this day it would be hard to find in a living form: and, in justice to this teacher and to that somewhat neglected school, I here acknowledge that whatever success has distinguished my practice I owe almost wholly to the doctrines I there heard expounded. (a)

In the district where I reside, and in the neighbouring cities, the past year has been, at least during the last nine months, decidedly one of little disease: remittent fevers prevailed during the first three months, but afterwards the cases of disease were few. It was soon remarked, however, that the inflammatory diseases of the chest had a certain character of gravity and of intractability, and the deaths were very numerous. In cases treated at the same time by other medical men, and where I was called in consultation, I had an opportunity of verifying these facts; as it happened that, in my own *clientèle*, such cases did not appear until afterwards. I, therefore, had already evidence of the great caution necessary in the de- traction of blood, even in cases of apparently the most violently inflammatory character, and also of the inconstancy of the effects of the various antimonials, when the first case presented itself to me. This was in a negro, healthy, and of middle age, who was attacked by pneumonia of

(a) I do not here, by implication or otherwise, advance any opinion as to the practice of the Vienna Hospital, which is by no means on a par with the University teaching.

the right side; a small bleeding was ordered in the arm, and cupping-glasses were applied; from these measures a temporary relief was obtained. Tartarized antimony was then given in moderate doses, but it was soon evident that the patient could not tolerate it; much diarrhoea came on, attended with delirium; great increase of the local symptoms, great dyspnoea, and high febrile symptoms. Warned by the results of other cases of which I had knowledge, I did not venture on further detraction of blood, but applied a large blister, and substituted the white oxide of antimony in Rasorian doses, with opium for the tartar emetic; the blister rose, and the white oxide of antimony was continued for two days. Tolerance was established, but the patient progressively grew worse: the sputa were at one time sanguinolent, at another of a purulent appearance; the patient passed his nights in a waking low delirium; the dyspnoea and local pain were great, the cough constant, the thirst great, and the heat of skin considerable. Seeing the patient thus, apparently, without hope if the usual treatment were persisted in, and perceiving a something in the compressible though rapid pulse, and the general character of the patient's symptoms, to assimilate his state to that of a person labouring under that condition of disease in which quinine is indicated, I resolved to despise all considerations drawn from the mere nosological classification of disease—and what, to many, would have been a still greater obstacle, viz., the state of the tongue, which was dry and tough as hide, and covered by a thick black crust—and prescribed twenty-four grains of sulphate of quinine with sulphuric acid, and one drachm of tincture of digitalis, to be taken in water, in divided doses, in the four-and-twenty hours. The patient was in the state described, and in the fifth or sixth day of the disease. He commenced the new medicine, and, after he had taken one-half the quantity above mentioned, there was an unhopèd-for and complete subsidence of all the symptoms; a refreshing sleep was obtained, the tongue became moist, the skin cool, the dyspnoea very much less, and the local pain reduced to almost nothing. The delirium did not reappear, and from that time a progressive amendment continued. The quinine was given at the rate of twenty-four grains per diem, until a complete cure was obtained; and the patient is now in perfect health.

Soon afterwards another similar case presented itself, which was rapidly reaching an acme like that arrived at in the former one, but rendered bolder by the result of that I did not hesitate so long in recurring to the use of quinine, which again produced effects as marked as those of antimony in ordinary cases of pneumonia. Other cases followed, in all of which, on seeing a continuance of the symptoms on the second day under the ordinary treatment, I prescribed quinine along with antimony and other suitable remedies, or alone; and in all I was rewarded by the same success; and I may add, that in those cases in which an active congestion of the pulmonary mass, rather than a true and frank inflammation, was present, the success of the treatment was the same. Of the preparations of antimony, the "Kermes mineral" was that which seemed to agree best with all the patients. I sometimes gave it from the commencement, with camphor and quinine. To satisfy an inquiry which many would be desirous to put, I state that, in Campinas, intermittent fever is very scarce; remittents occur at certain seasons, but did not coexist with these cases of pneumonia; and in the neighbourhood there are no swamps, though there are virgin woods in which clearings are being always made.

The state of things which imparted the type in question to pneumonia is here exceptional, and in other parts of Brazil, where it might be with reason expected, does not exist; though it may, as an extraordinary medical constitution, do so at any time, as well as here. One might, instead of invoking the explanation of these facts which the above-mentioned law offers us, merely recite them as evidences of the hyposthenating

powers of quinine, asserted by the Italian school; and indeed, in the circumstances referred to, they were proved truly to exist; but I do not think myself justified in concluding from the present cases that they generally and universally exist, though that they may do so I do not deny. As a law exists by which the results obtained are explicable, to seek for other causes would be highly unphilosophical; as it would also be under ordinary circumstances, were any one to neglect to put in practice the usual antiphlogistic treatment on pneumonia, or the Rasorian modification of it—deviating from it so far only and according as sound medical judgment and a careful consideration of the attending circumstances and character of contemporary disease generally warrant. Had this caution been more carefully observed, many instances of the instability of systems and downfalls of brilliant theories of modes of treatment—flourishing for a time, and then universally abandoned—would have been prevented from occurring to discredit the character of the profession for sound reasoning. May it not be most probable that the emetic treatment of Maximilian Stoll, the application of antimony in high doses in acute disease by Rasori, the depletive treatment of Broussais—all owed, in great part, their temporary triumph to their being severally brought forward under the existence for the time of an epidemic medical constitution which demanded an analogous treatment? Such an explanation offers at least an apology for the temporary furor with which they were welcomed by the mass of practitioners, and for the abandonment to which, in part, they have since been consigned: though each of such systems ever leaves a legacy of some useful innovation in therapeutics which is never wholly lost.

SINGULAR CASE OF CEREBRAL DISEASE.

By THOMAS BROWN, Esq., Surgeon, Castle Donnington.

I was requested to visit Samuel Holmes, a labourer, aged twenty, living at Weston-on-Trent, on the 19th ult. I found him sitting by the side of his bed, evidencing a dread of either moving his body or turning his head, and on doing the latter, he described the symptoms and sensations which characterize vertigo. His mental emotion is very great, the slightest noise (even the falling of a pin) producing nervous excitability and confusion in his brain. He is of the middle stature, has blue eyes, contracted pupils, and light impoverished hair; his appearance is peculiarly idiotic, and there is evident deficiency in the anterior and superior convolutions of the brain; the eyes wander and look vague, giving a vacant expression to the countenance. He complains of an illusive sound like the rippling of water through his veins, and he imagines the presence of this fluid the sole cause of his ailment. He is very unwilling to make the slightest exertion, loves the most perfect quietude, and has only been induced to leave his bedroom a few times in as many months. His intellect is unimpaired, though I should judge it was always of an obtuse kind. His general health is tolerably good, and has continued so during the whole time of his disorder. He first perceived himself the subject of morbid action in January of this year, and has consulted several medical gentlemen, but no hope was held out to him of recovery. Without supposing it probable that I should be capable of rendering my patient any permanent benefit (suspecting cerebral lesion), I felt justified in treating the case as one of an inflammatory kind. I had the hair removed from the scalp, and ordered the constant application of an evaporating lotion; extracted some blood from the temporal region, attended to the proper action of the hepatic and other viscera, and established a double persistent seton in the nape of the neck. At this time (July 20) some improvement has taken place, and all the symptoms

are much modified, yet I fear he will remain through life the victim of a miserable and obscure disease.

CASE OF PUSTULAR DISEASE, ALLIED TO VARIOLA, AFTER VACCINATION.

By J. E. PATHSON, Esq., M.R.C.S., Islington.

There are no cases of disease perhaps more puzzling in their diagnostics than those of an irruptive character, and none which the general practitioner is called upon so suddenly to give a being and a name to. For every variety of rash (and their name is legion) that a mother sends for you, generally in a hurry, to see on her child, she desires you at once to give it a name, ere you have scarcely had time to inquire into any of the ordinary symptoms, much less to settle in your own mind the exact nature of the disease, which not unfrequently requires days to develop itself into nosological being.

These reflections arise from a case I was called to a few days since, in attendance on a little patient, the daughter of the Rev. E. C., whose symptoms I shall particularize without even now presuming to give a name to the disease that afflicted her, especially as the eminent physician who was called in, the clergyman himself (a gentleman, I may note, not a little skilled in medical science), and myself, a general practitioner, held each different opinions as to whether the disease was chickenpox, modified smallpox, or a distinct disease to which the name varioloid is sometimes applied. By the term varioloid I do not mean a form of variola modified by previous vaccination, but a disease disconnected altogether with variola, which was known long before the introduction of vaccination, and which is treated as such in the annual reports on vaccination in France, where MM. Honoré and Double, and other members of the academy, state that varioloid was known as a distinct disease long previous to the time of Jenner.

M. Bayer, too, writing on the varioloid, states that occasionally it makes its appearance in persons who have already had the variola, or been vaccinated, or inoculated; and is also developed in persons who have not had either the cowpox, or the natural or the acquired smallpox.

In the case of my patient, whose symptoms, taken together, as will be seen, are characteristic neither of smallpox nor cowpox, the disease, by whatever name we call it, was not quite devoid of danger: the young lady, the subject of it, was about seven years of age, and remarkably healthy looking. She had been vaccinated in her infancy, and had the characteristic cicatrix mark on her arm; but whether she had the constitutional or protective fever during the vaccination I could not learn. The symptoms first noticed were simple fever during the day, increased towards evening, and on the night of the same day of attack, considerable cerebral disturbance, amounting to violent delirium, came on, and towards morning a suffused rash appeared. On being sent for and questioned as usual as to the name of the disease, I answered as well as I could evasively, which meant in plain English, "wait a wee": for from the sore throat which the child suffered from, and suffused red patches, I was apprehensive of scarlatina, though the tongue showed no indication of that disease, as it was coated only with the white fur of simple fever.

Previous to my arrival, the father had wisely administered proper antiphlogistic remedies, so that the delirium and brain excitement had disappeared.

On the second day of the disease the symptoms had changed in character, the eruption becoming more marked—more, in fact, like distinct variola; thus the papule were sensibly elevated above the surface of the skin, were circular, distinct, and distended, and had spread over the whole body; the intervening spaces in some parts were red, in others not. The eruption, however, in the ordinary distinct variola, does not generally come out till the fourth or

fifth day, so that, although it was like it in character, it was different in its development. The throat had been sore from the commencement of the attack. On the third day the eyes became suffused, and the general febrile symptoms increased in intensity; red patches appeared in different parts of the body, remained out for few hours, and again disappeared. The fur on the tongue assumed a brown appearance, but was always moist.

On the fourth day many of the papulae were seen to be depressed in the centre, were filled with a limpid fluid, and had every appearance of the variolæ papulae; the fever, which had till this date ranged high, was now very much lessened the swelling of the throat, however, became more troublesome, and deglutition difficult, so that the little sufferer was very much incommoded by it. The suppuration of the papulae progressed favourably, and the fever on the fifth day had entirely disappeared, so that she was now convalescent.

The treatment adopted was simply to moderate the fever and let the patient have plenty of fresh air, acidulated drinks, and saline purgatives the soar throat was pencilled with caustic, which the little patient, who was remarkably sensible and docile, was easily persuaded to have done as often as required.

Now, it becomes a question as to what the exact nature of this disease was: it most surely was not the chickenpox, as the fever in that disease is slight, the pustules, too, in varicella never suppurate; whereas, in the case we have described, there was evident suppuration of the pustules. It presented, also, many symptoms which are not observable in ordinary variola, or smallpox after vaccination, such as the scarlet patches which now and then were noticed. However, it matters little what name be given to the set of symptoms, but we see that occasionally there a very virulent disease may afflict the human body, even in spite of vaccination's protective powers; yet, even allowing this, our faith in Jenner's glorious antidote should not at all be lessened, as it is not an unfrequent occurrence even of genuine smallpox attacking the same individual twice, as is noticed in the ordinary vaccine reports; and in respect to lymph, it becomes a question whether it should not oftener be renewed from the cow, and even the vaccine disease itself be renewed, as in the admirable experiments of Mr. Ceeley, to whom is justly due the great merit of proving Dr. Jenner's proposition of the real identity of the cow and small pox.

Barnsbury-road, Islington, July 27.

FOREIGN PRACTICE.

Reported for the MEDICAL TIMES by ALFRED MARKWICK, Esq., Surgeon to the Western German Dispensary, and formerly Externe to the Venereal Hospital, Paris, &c.

SUPPURATED BUBO TREATED BY INJECTIONS.

The following is a summary of a memoir lately published by M. Jules Roux, of Toulon, in the "Archives Générales de Médecine," on a new and hitherto very successful mode of treating suppurated buboes, which consists in injecting into the cavity of the abscess, after the pus has been removed by a subcutaneous puncture, one of the following preparations:—

1. Tincture of iodine, composed of iodine, 30 grammes; alcohol, 100 grammes.

2. Tincture of iodine of the codex, composed of iodine, 8 grammes 33 centigrammes; alcohol, 100 grammes.

3. The above, No. 2, diluted with twice its weight of distilled water.

4. Alcohol at 30°.

5. Alcohol, diluted with twice its weight of distilled water; solutions of 50 centigrammes of nitrate of silver in 30 grammes of distilled water; of 1 gramme of corrosive sublimate in 100 grammes of water; and, lastly, one of common salt, were also used in a few cases, but they did not answer so well as those of which iodine formed the basis. The fluid having

been injected, its evacuation is facilitated by pressing the tumour, a small quantity, however, remaining within the cyst being immaterial. The operation is said to occasion great pain, but has never given rise to any unfavourable symptoms. Sometimes a small puncture may be necessary to evacuate some freshly-formed pus; but, generally speaking, the tumour subsides, and the parietics of the abscess become speedily agglutinated together.

M. Roux states that the quantity of either of the above fluids never exceeded forty grammes for an injection, and that all the patients submitted to this method have undergone a general mercurial treatment.

The cases in which injections may be resorted to are those in which the bubo is beneath the aponeurosis, and its parietics are of sufficient consistence that we may anticipate their agglutination; those in which they are contraindicated are where the tumour is superficial, as in that case a cure is more easy to be obtained without resorting to an injection; and, secondly, where the skin is red, thin, and about to ulcerate.

The results obtained by M. Roux are as follows:—Out of 70 cases 35 were cured without any fresh formation of matter, in, on an average, 17 days. In 17 there was a reformation of pus: the average date of recovery being 22 days. In 18 cases there was either partial or extensive ulceration over the surface of the tumour, in 1 of which the actual cautery was necessary. Taking the whole 70 cases, the mean duration of treatment was 21 days.

19, Langham-place.

A CASE OF CONGENITAL PHYMOSIS.

By OCTAVIAN ROYLE, M.D.

The mother of the child in question applied to me, in the early part of last month, under circumstances which I will briefly illustrate. Her child, she stated, had for several years past oftentimes experienced great pain, heat, and difficulty of micturition, with a great deal of oedema about the frenum, and irritation of the orifice of the urethra, together with a slight gleet discharge. The constriction of the prepuce was almost complete, only sufficient to admit the point of the little finger, although on either side of the frenum it was detached, so as to enable the easy introduction of the probe; here, occasionally, appeared two small vesicles infiltrated with serum, which, according to the boy's own account, caused excruciating pain whenever he made the attempt to empty his bladder; and it was from this circumstance solely, I believe, that induced the mother to adhere to my suggestion, viz., of dividing or dissecting back the prepuce. On the division being completed, the glands, as might be anticipated, presented a very unnatural and unhealthy aspect, which, however, soon yielded to the local application, viz., "hydrargyri chloridum gr. vj. ad ℥j. liquor calcis." This produced a very copious discharge for the first 20 days; but the subsequent beneficial effect of a repetition was very marked and decisive, for upon the morning of my fourth visit the parts had entirely healed, coupled with a simultaneous subsidence of the symptoms hitherto experienced. I should add, the mother had on several previous occasions applied for advice, and Mr. Allhill, her medical adviser, had explained to her the mode in which relief might have been obtained; but, from her strong aversion to surgical interference, she would not, until the present time, submit to anything but palliative treatment.

Ipswich, July 29.

CASE OF STRANGULATED INGUINAL HERNIA IN THE FEMALE, WITH OPERATION.

By B. W. BROWN, Esq., Wymeswold, Leicestershire.

On the 23rd of April last, I was summoned to visit Mrs. Orson, of Rempstone, a village distant two miles. She was seventy-one years of age,

and it appeared she had been ruptured on the left side for more than six years; and she had also procidentia uteri of some standing. I had on a former occasion—ten weeks ago—attended her; she was then suffering from constipation of the bowels, and was relieved in a few hours by some active purgatives. She had never suffered any great inconvenience in consequence of being ruptured, and therefore the fact of her having been so for six years she had not at any time made known, except to her daughter. On the present occasion, however, after a slight attack of diarrhoea, she was suddenly seized with a severe pain in the stomach, which alternately increased; the bowels had not been moved for several hours; there was constant retching and vomiting of bilious matter, attended with fever and thirst; the tongue excessively furred; an irritable and intermittent pulse, without tension or pain of the abdomen on pressure. I was now, on inquiry, for the first time informed of "a swelling" at the lower part of the abdomen, and upon examination discovered an irreducible oblique hernia: it was very soft and yielding. Sedative salines were given to allay the thirst and arrest the vomiting; alternate doses of calomel and extract of colocynth, castor-oil, &c.; these were successively rejected by the stomach. I now ordered a turpentine enema, to be repeated every four or five hours, if necessary, in order that the rectum and lower bowels might be well emptied; the two first injections brought away a quantity of scybala, giving some temporary relief as to the urgency of the symptoms; the calomel and colocynth were repeated with the salines, which remained on the stomach several hours, but were ultimately rejected, without any further movement of the bowels. I now gave the hydrocyanic acid with the saline every four hours, continuing the injections; the vomiting was again stayed for many hours. One might have suspected this to have been a case of intussusception.

On the 28th the bowels had not been moved; the sickness returned, but not so urgent; the hernial tumour remained the same—soft and yielding, nor was there any preternatural hardness of the abdomen; and, therefore, I did not as yet feel myself justified in resorting to the last remedy—an operation for strangulated hernia. The same remedies were persevered in, and a mild spirit lotion was now constantly applied to the protruded part; the warm bath was used with the like result.

On the 29th, six days from the commencement, no evacuation *per anum* had taken place, except by the two injections as before stated; the vomiting had now returned with increased violence, large quantities of feculent matter were thrown off from the stomach, the abdomen had become tympanitic, and the hernial tumour was exceedingly tense and somewhat discoloured; hiccup had supervened; there were now all the symptoms of strangulated hernia, which nothing but an immediate operation could relieve. The operation was at once proposed to my patient and her friends, as the only means left to save her life; she at once consented. My excellent and valued friend, Dr. J. C. Williams, physician to the Nottingham General Infirmary and Lunatic Asylum, now arrived, and the operation was resorted to without delay. Mrs. Orson being then placed in the usual position on a large sofa, I commenced an incision, at least one inch and a half beyond the ring, and extended it to the base of the tumour, which was nearly twice the size of a cricket-ball; this laid bare the fatty tissue and several arteries; a large vessel was seen to cross the neck of the tumour, which, being divided, bled somewhat smartly; the fasciæ being divided, exposed the hernial sac, which exhibited considerable vascularity, and was of a dark-brown colour. As the hernia had existed so long, I anticipated here would be plenty of adhesions, and some difficulty in destroying them; I, therefore, did not think it prudent to divide the sac its whole length, nor would it have been wise to have unnecessarily extended the incision over so

large a portion of serous surface; a small opening was made immediately below the ring; but I could neither introduce the director nor my finger-nail beneath the stricture—intestine. As I have invariably done in an operation of this kind, to have divided the stricture directly upwards; so extensive and firm were the adhesions that every attempt was here fruitless. The only alternative I had now left, was carefully to dissect and divide the stricture *from without*; so numerous, however, were the membranous bands crossing and intersecting each other, duplications having been formed between the protruded bowel and omentum, and so strongly were they all glued together, that, whilst one of these remained undivided and undetached, the strangulation was not relieved, nor could the contents of the sac be returned. The intestine, which contained some indurated feces, and the omentum had become entangled—the latter very firmly embraced the former, and a portion of the former had become doubled up over the latter, and were closely adherent to each other; they were separated and placed right; the adhesive bands were carefully detached, and I readily succeeded in returning the protruded volume into the cavity of the abdomen. Three sutures were applied, with strips of adhesive plaster, and Mrs. Orson was placed in bed. The sickness and hiccough had now ceased, and in less than twenty minutes after he was placed in bed the bowels were very freely moved, and again during the night. On the following day every unfavourable symptom had disappeared.

On the 9th the sutures were removed; and, on the sixteenth after the operation, Mrs. Orson became convalescent, and is now doing well.

My thanks are due to Dr. Williams for the assistance he rendered me during this very intricate and perplexing, as well as dangerous, operation. The adhesions being so numerous, and extending along the whole of the inguinal canal, and even beyond, required considerable nicety and care, lest the bowel should be injured. I believe there is some little difference in the operation for inguinal hernia in the male and that of the female. If I recollect right, when listening to Sir Astley Cooper in the theatre of St. Thomas's Hospital, he advised his pupils, in the operation for strangulated inguinal hernia in the female, to avoid opening the sac further than immediately below the ring, sufficient to admit the director; and he gave very satisfactory reasons for so doing, mentioning several cases. In the present case, as the parts have been so freely scarified during the operation, in all probability the canal will be permanently closed, and thereby hernia prevented in future. It should be observed, in closing this account of an interesting case, the pulse here was no direct guide—it was exceedingly tremulous: now quick, then scarcely perceptible and slow; then for several seconds no trace of pulse could be felt: this is usually the case in Mrs. Orson. As for several months past there has been cedema of the extremities, no doubt there is some organic disease of, or near, the heart, or of its vessels, which may account for this singular state of the pulse.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of July 26; M. BROWNIAU in the Chair.
POISONING BY VOLATILE SUBSTANCES. By M. FLANDIN.—The science of toxicology has, since the last ten years, progressed rapidly, and its advancement is chiefly observable in the history of mineral poisons. Chutison, Orfila, Berzelius, Dumas, Devergie, and others have directly pointed out the process by which arsenic, copper, lead, &c., may be extracted from the body after dissolution, and even after prolonged inflammation. But the presence of vegetable poisons in the organs is much more difficult of detection, and hitherto no chemical method has been in-

deated by which their existence in the system can be ascertained with any degree of precision. The great frequency of poisoning with opium, and the principles extracted from opium, rendered it highly desirable that the practical researches of chemists be directed to this subject. M. Flandin, well known for his numerous and interesting publications on the subject of arsenic, endeavouring to fill up the chasm, read to the academy the first part of a work on poisoning by vegetable substances, treating more particularly of opium and morphia. The analytical method recommended by the author is founded upon the two following remarks:—viz., 1. "Morphine, narcotine, strychnia, brucine, are not decomposed, when in contact with animal matters by a heat slightly superior to 100° (212° F.);" and 2. "Ammonia decomposes the acid solutions of these vegetable alkalis, and causes their precipitation. Hence the substances to be analyzed should be dehydrated at a temperature below 115° (239° F.), and afterwards reduced to a fine powder and dissolved in spirit acidulated with oxalic acid, or in weak acetic acid: from these solutions the vegetable alkali can readily be separated by the addition of ammonia."

ACADEMY OF MEDICINE.

Meeting of July 27; M. BÉGIN in the Chair.
MINERAL SPRINGS.

A long report on the mineral water of Balaruc was read to the academy by M. Isidore Boudou, and occupied nearly the entire meeting. Balaruc is a small village, situated at a few miles south of Montpellier, and celebrated for a thermal spring, the mineral elements of which are chiefly chloride of soda about 5ij. per litre and carbonate of lime (20 grains). The heat of the water is 17.5° (63.5° F.). Paralytic affections, whatever their cause, rheumatism, and partial ankylosis of the joints, are the disorders for which patients usually resort to Balaruc.

After a long investigation into the stricture, brought forward by the physicians of the locality in support of the virtues of the waters, the reporter, acknowledging that their singularly favourable action might in these statistical accounts have been slightly exaggerated, still maintained the very great utility of the waters; and the Minister of War, having inquired if it would be expedient to establish on the spot a military hospital, M. Boudou was inclined to propose to the academy to make an affirmative answer.

M. Malgaigne remarked that, as far as the question of partial ankylosis was concerned, he did not consider it was correct to praise the efficacy of any mineral spas whatever. One method of treatment alone was of any use, and consisted in exercise of the joint. Without exercise, mineral waters were unavailing: with exercise, they were superfluous. In the year 1840, M. Rigal, a surgeon, came to Paris for a dislocated shoulder, which had resisted nineteen attempts at reduction. M. Malgaigne had the good fortune of replacing the articulation, but very considerable stiffness prevailed for a long time, and was dispelled only by persevering and most painful exercise. Dr. Rigal had at first expressed a hope that he might dispense with this great suffering by resorting to some mineral waters, and was much struck with M. Malgaigne's decided objection to this mode of treatment. Dr. Rigal had since then—his attention being thus directed to the subject—followed up several cases of partial ankylosis at mineral springs, and was now perfectly convinced of their absolute want of efficacy when used alone, and without proper exercise of the affected joints.

M. Lallemand had, for upwards of twenty years, studied the effects of the waters of Balaruc: he had found them injurious in paralysis caused by cerebral disorders, and useful, on the contrary, in maladies connected with debility, want of tone, or a scrofulous constitution.

CATARACT OPERATED BY SUCCION.—A case was then presented to the academy by Dr. Blanchet; it was that of a man, aged thirty-

two, who, being affected with a soft cataract, was operated by suction ten days ago. In previous communication we have described the *modus operandi* of this new method of treating the cataract, and we stated it to have been revived by Dr. Langier and Professor Bousquet. In the present case success had been complete, and vision was restored.

Meeting adjourned at a quarter past five P.M.
ORGANIC DISEASE OF THE HEART, DYSMURIA OF THE BICUSPID ORIFICE, AND ARREST OF CIRCULATION IN THE LOWER EXTREMITIES.

By PROFESSOR SHUTZENBERGER, OF STRASBURG.
CASE.—At the age of twenty, Peter P., a shoemaker, was admitted into hospital for acute rheumatism; his illness lasted one month, and he was dismissed cured—at least in appearance. During two years his health remained excellent, but at the end of that time palpitations and dyspnoea showed themselves; blood was expectorated on six different occasions, and in September, 1846, infiltration of the lower extremities occurred. The anasarca was relieved, but the palpitations and dyspnoea persisted. Four years had now elapsed since the original attack of rheumatism, when, on February 10, 1847, the patient was suddenly seized with vertigo and sickness, and at the same time with a painful sense of numbness in the lower extremities, together with impossibility of moving them. He was brought to the clinical wards on the morning of the 11th, and on examination, the impulse of the heart was found to spread to a considerable surface; its pulsations were weak and irregular; the dullness on percussion occupied fourteen centimetres in every direction; the sounds of the heart on auscultation were, as it were, stifled, and a souffle was found to coincide with the first bruit. The arms and hands were in their natural condition. The pulsations of the carotid, and of the radial arteries were remarkably weak. The feet, legs, and the lower third of the thighs were of a dark livid colour, considerably infiltrated, cold, almost immovable. The crural and popliteal arteries were carefully sought for, and were the seat only of an almost inappreciable tremour. The patient was bled, cupping was resorted to, opium was exhibited for the purpose of hushing the pain in the legs, and warm fomentations were employed to restore, if possible, the circulation in the crural and tibial vessels; but the symptoms continued to increase in severity, a hard cord appeared on the course of the femoral veins and arteries, broad patches of ecchymosis and phlegmon were observed, and a gangrenous eschar was noticed over the internal malleolus of the left leg. On Feb. 20 the patient died.

On dissection, two ounces of transparent serum were found in the pericardium; the heart was considerably enlarged, its left cavities and also the right auricle being distended by coagulated blood; the aortic orifice was free, and the bicuspid tightened by the thickening of its valves, which was not, however, ossified. In the right auricle were found several fibrinous concretions, and one of them extended as far as the right crural vein. The right iliac artery was obliterated by an adhesive clot which extended throughout the vessels of the limb, down to the anterior tibial below the annular ligament of the ankle. The same alteration, only beginning at eight centimetres from the bifurcation of the aorta, was observed in the left iliac. The veins were likewise obliterated; the lungs congested; brain and spinal cord healthy.

Strictures of the cardiac orifices do not generally, says Dr. Shutzenberger, produce in distant parts so complete an arrest of circulation; in the present case, however, it may be explained by the diminution of the column of blood propelled into the arteries, which slackened the capillary circulation, and ultimately brought on its arrest in the parts most exposed to it by their dependent position.—*Gazette Médicale.*

AMAUROTIIS CAUSED BY SATURNINE INTOXICATION. A house-painter, aged forty-six, was two years since attacked with colica pictorum; four months ago he was admitted in the hospital for

symptoms of hemeralopia, which followed another manifestation of the colic, and which disappeared under the influence of a purgative course of treatment. During the month of July he was again received into hospital suffering from a recurrence of the ocular disease—viz., in the evening, the darkness really set in, he became almost blind, and artificial light—lamps, candles, &c.—was seen very indistinctly, and appeared of a red colour. The treatment instituted was that usually employed against saturnine affections, and a speedy amelioration was obtained.

An excellent memoir by M. Duplay we find some details on saturnine amaurosis, which it may not be uninteresting to reproduce, as the hemeralopia observed in the case above briefly recorded must be considered as a sort of partial gutta serena. That form of amaurosis which is produced by the introduction of lead into the system is generally sudden in its appearance, mostly follows several attacks of colic, coincides with articular pains or paralytic symptoms, and readily yields to a proper treatment. From the limited statistics brought forward by M. Duplay, the duration of saturnine amaurosis is not on the average more than eight or ten days. M. Andral records a case of diplopia which followed an attack of colica peticum, and yielded to purgatives; and in a German thesis, by Dr. Vaton, we find a case of hemiopia due to the same cause: for a long time the patient could distinguish only one half of the objects which he looked at. These various alterations of the visual function may be classed amongst the latest symptoms produced by saturnine intoxication, and all belong to the same order of disease—"neurosis."

MIDWIFERY.—What is the object of the accoucheur in supporting the perineum at the conclusion of labour? It is to retard and render gradual the dilatation of the parts in order to prevent laceration. Professor Dubois thinks the same object may be attained by introducing three or four fingers joined together, and by pressing against the head of the fetus. The learned professor considers that the generally adopted practice of supporting the perineum by pressure interferes with its circulation, and may be the cause of unpleasant consequences.

HOPITAL SAINT LOUIS.

PELLAGRA.

D., a carter, aged twenty-five, during the spring of 1845 noticed on each cheek a circular red patch, which gradually invaded the entire extent of the cheeks. This redness was attended with some slight itching and heat, and some general symptoms of trifling importance, such as a sense of lassitude and diminution of appetite. During the ensuing winter these accidents disappeared, but returned with exactly the same characters in the spring of 1846. Again, on the return of winter the eruption subsided, but recurred, and with a different series of morbid manifestations, in the early months of the spring of this year. The cutaneous eruption acquired only a very slight degree of intensity, but the digestive and nervous systems became for the first time the seat of important disturbances. On June 10 the patient was, without apparent cause, seized with violent headache and giddiness, which, increasing daily, obliged him on the 13th to cease his avocations. On the 16th he was admitted into Hôpital Saint Louis, in the following condition:—The face was thin and drawn, the eyes bright, and on each cheek were noticed patches of a brownish red, covered with scales of desquamation; itching and pain, chiefly on exposure to the sun, were also present. No other alterations existed on the skin of the other parts of the body. The appetite was destroyed; the tongue foul, and scarlet near its edges; the bowels irregular and rather relaxed. Along the spine and in the lumbar region the patient complained of an unpleasant sense of formication. The legs were weak, their motions uncertain, and great unsteadiness was observed in walking; cramps were present in the arms and lower extremities; the pulse at 84.

Leeches were applied to the seat, and with the assistance of a mild diet the patient was discharged cured on the 2nd of July. We should not omit to add, that the gums were throughout tumefied and red, and the salivary secretion increased in abundance.

The return of the eruption of the face at each consecutive spring—its connection with other symptoms, such as the redness of the gums, salivation, disorder of the digestive functions, loss of power over the extremities—was the principal ground upon which M. Devergie founded his diagnosis of pellagra. Erythema solare is local disorder; scorbutus is attended with ecchymosis in various parts of the body, but the group of remarkable symptoms united in this case induced M. Devergie to admit that he had to do with a disease differing materially from the other case.

This disease has generally been divided, for descriptive purposes, into three periods: in the first, lassitude, dyspepsia, thirst, melancholy, headache, and pains in the back, together with a slight cutaneous eruption which disappears with the return of the warm weather, are the leading symptoms. The second is marked by the greater intensity of the same phenomena; diarrhoea, vertigo, weakness of the limbs, and sometimes clinical, their appearance. The skin acquires a dark colour, and the epidermis falls off in scales. This condition may last for many years without any evident increase. But in the third and last period the skin becomes exquisitely painful, diarrhoea is more frequent, the pulse small and quick; vision is disturbed, and paralysis may be observed; at the same time emaciation progresses, and a tendency to self-destruction is noticed. On post-mortem examination, the most important changes are anatomic lesions of the cerebro-spinal axis (induration or softening), by which the nervous symptoms existing during life may be accounted for. With regard to etiology, the disease is by some attributed merely to exposure to the sun; by others to insufficient diet, and particularly to the use of Indian corn—an opinion which, however, is far from general. It is only in the third period that the malady is beyond the reach of art; during the two others a judicious treatment of the symptoms is generally productive of a satisfactory termination.

A NEW MODE OF RECOMMENDING A QUACK MEDICINE.

A M. Deschamps forwarded some weeks since to the Academy of Sciences the following recipe for a purgative "syrup," which he considers as a panacea for the most various diseases; for instance, gastritis, herni-crani, tooth-ache, cholera, ague, and consumption.

R. Pulveris jalape, 28 grammes (℥j.); anisi, 6g. 39 (℥jss.); macra per desicc. in spirit rectif., 200g. (℥vj.); agite, sac-sapinilla, 200g. (℥vj.); pulv. ther., 50g. (℥jss.); serpentaria radiceis, 37g. 50 (℥ix.); sassaapar. filae, 50g. (℥jss.). Decoque per horis ij. in aqua, O. viij., adde coll. semina, sac-saparas radiceis, aa. 100g. (℥iv.). Mucra in decoctione, coll. adde sacchari comm., lb. iv.; meli carbon, lb. j.; f. s. a. syrup; mix the alcoholic infusion with the syrup. A table-spoonful for a dose to be taken seven hours after a meal.

The most curious part of the history of this most complicated "panacea" is that M. Deschamps has lodged in the hands of M. Arago securities to the amount of £3000, which he consents to forfeit in case his universal remedy is not found efficient.

D. MCCARTHY, D.M.P.

The Influence of the Brain and Spinal Marrow on the Heart.—Dr. Julius Budge, the celebrated physiologist, has arrived at the following results in reference to this subject: That the spinal marrow is the central organ for the heart's movements, inasmuch as it maintains the irritability of the voluntary muscles; that the medulla oblongata is the central organ for the reflex movements of the heart; that the ganglionic system is not the central system for the

heart's movements, but appears to modify the influence of the voluntary and reflex principles.

Benzoate of Ammonia in Gout.—Dr. Seymore states that he has frequently used this medicine in cases in which the small joints were red and swollen, or where fluid was deposited in the joint of the great toe; and also in cases where the lithate of soda existed in the joints of the fingers, with success. He thinks that, under the use of this medicine, early depositions have been arrested, and large depositions diminished. In dropsy, where the stomach is so irritable as to render the employment of ordinary diuretics impracticable, he regards the benzoate as peculiarly applicable. He has also seen, during the use of this medicine, the albumen in recent dropsy diminish.

Properties of the Iberis Amara.—Dr. Silvester read a paper on the properties of this plant, commonly called candytuft, at the meeting of the South-Eastern Branch of the Medical Association. It appears to have been first used by the late Dr. Williams, at St. Thomas's Hospital, in cases of asthma, bronchitis, dropsy, and more especially cardiac hypertrophy, with the best results. It does not diminish the velocity of the heart's action, like digitalis, but controls its violence and sharpness, and thus softening the force; hence its great value in hypertrophy with dropsy. Dr. Silvester says that he has found, after an experience of ten years, that it may be used with some benefit, nearly always, in the above-mentioned diseases, and sometimes with almost magical efficiency. It occasionally produces giddiness, sickness, or diarrhoea; but subsides on discontinuing the medicine.

The dose prescribed was from one to three grains, generally mixed with cream of tartar, which concealed the nauseousness of the taste, and cured a perfect tituration and division of the high seed. There is an incidental proof, in Linley's "Introduction to the Natural System," of the correctness of the belief that the order *Cruciferae* contains many plants of value in the treatment of asthma and dropsy. It is there said that Plinius Maximilian, of Wied Neuwied, relates of the Brazilian Indians, that they used a kind of cress, resembling that of Europe, as a good remedy for asthma. The *iberis amara* is a true cress.

Arsenic in Cancerous Diseases.—Mr. Hunt, of Lorne Bay, has seen some well-marked cases recover under the use of arsenic, and which, systematically administered, checks the disease in every stage. The liquor potassae arsenitis of the Pharmacopoeia was the form used, in doses of five minims, three times a day, on a full stomach; the dose to be reduced on the occurrence of conjunctivitis.

Tracle in Burns.—Dr. Payne, of Nottingham, says, that for upwards of twenty years he has used tracle in the treatment of burns and scalds. It is applied pure on the injured surface, and at the natural temperature, folds of well-aired linen being laid over it, and the dressing allowed to remain for three or four hours at first, when the tracle will be found in a more fluid state—hot to the touch, and the rag saturated with it. The tracle is then applied in the same manner, but after the second or third day of the burn will not require renewing oftener than once or twice daily, and the tracle will now begin to preserve its usual consistence while in contact with the abraded surface. The time occupied in healing is very much less than is the case when any other means are employed. No remedy, Dr. Payne considers, can exert more beneficial effects, and that life may be preserved in the most desperate cases by the timely and free application of this invaluable remedy. It acts by effectually excluding the air, and (as appears by the fact of the pain entirely abating, or greatly diminishing, as soon as applied) by abstracting the morbid heat from the part, and thus proving at once sedative, refrigerant, and healing.

Turning in Distortion of the Pelvis.—Dr. Radford says, in the *Provincial Medical and Surgical Journal*, that before recourse should be had to turning the child, to suprapubic craniotomy, or other

instrumental means, we should be satisfied that we do not create equal, if not greater, evils. The first question to be settled is, can we safely turn and deliver the child? Here is involved a due estimate of the degree of distortion of the pelvis relatively to the size of the child's head, and likewise the condition of the maternal organic structures. Can we always deliver by turning? Certainly not. It would be highly culpable to attempt turning with the passages undilated and undilatable, or when the liquor amni has been some time discharged. Under either of these circumstances the child would perish. Does turning give the child a better chance than might be afforded by other measures? As regards the crutch, the answer is plain; but the long forceps, in the great majority of cases of slight contraction of the pelvis, may be more advantageously had recourse to. Will the head pass through a less pelvic space when its base comes first, as in footling cases, than when the vertex presents? It will not, unless such unwarrantable force is used as to risk the separation of the body from the head, leaving the latter in the uterus. Does the head elongate more readily upwards than downwards? If only the same degree of extractable force is used, it does not, and certainly not so safely to the child. But assuming that the child's head elongates as readily, if not more so, in footling cases, than in presentation of the vertex, we know that the funis is subject to fatal compression in the former—which danger is greatly increased in cases in which the child has been turned on account of distortion of the maternal pelvis. Can the head of the child be adjusted and better adapted to pass through the widest portion of the brim of a distorted pelvis, by means of the leverage its body affords after it has been turned, than by any other means? Velpeau has great reliance on the advantages of turning in these cases; but, unless all contingent circumstances are favourable for its performance, the operation is most certainly hazardous to both mother and child.

Sacculated Oesophagus with Stricture.—Mr. W. C. Worthington read an account before the Suffolk Branch of the Provincial Medical and Surgical Association, of a case of this uncommon disease. The patient was a gentleman, sixty-nine years of age, robust, with an enormous appetite, which he indulged during the greater part of his life. Three years before his death, he suffered from slight dysphagia for eighteen months, without any apparent aggravation. Four or five months before he was brought under medical treatment, there existed considerable difficulty in swallowing solids, accompanied with emaciation. A probang was introduced into the oesophagus, which became obstructed at or near the cricoid cartilage. This operation was repeated at intervals, without getting beyond the supposed seat of stricture. Eventually the patient became totally incapable of swallowing food, and at length died. On a post-mortem examination, a pouch or bag was discovered proceeding from behind the oesophagus opposite the cricoid cartilage, which must have hung down between the trachea and cervical vertebra. Nearly two-thirds of it were covered with muscular fibres derived from each of the constrictors, which were much stronger and more developed than in health. The entire pharyngeal cavity was found dilated far beyond what is natural. Immediately behind the cricoid cartilage, and opposite the commencement of the pouch, there existed in the oesophagus a stricture, formed by a transverse fold of the mucous membrane, and which would only admit a large-sized urethral bougie. The oesophagus below was contracted, but its mucous membrane throughout healthy. Had the nature of the disease been detected in its earliest stage, the stricture being caused simply by the contraction of the mucous membrane, there is no doubt it might have been easily made to dilate by the careful use of bougies.

Calcareous Deposit in the Arteries at the Base of the Brain.—Mr. Norman exhibited to the Bath

Pathological Society the brain of a man, seventy-five years of age, who had suffered for six years before his death from what seemed an apoplectic fit; he recovered perfectly, but was subject to threatenings of a similar nature, which were apparently averted by depletion. On Jan. 1, he had an attack followed by insensibility and perfect paralysis of the left side, and in forty-eight hours he died. On dissection there was found a large clot of coagulated blood, occupying chiefly the right lateral ventricle, the pressure of which against the roof gave rise to the appearance of softening; but which, on a section of the nervous matter, such was not the case. Some blood was found in the left lateral ventricle, but the source did not appear. The arteries at the base of the brain were much diseased, especially the basilar, which was merely a rigid tube from the deposition of calcareous matter.

Structure of the Nerves.—The researches of Ehrenberg and his successors in histological inquiries have satisfactorily shown that the nervous fibrils are tubular, and not simple threads. What do these tubes contain? What is the structure of the walls? The nerves of the crayfish, when compared with those of men, are like sacking compared with fine linen. The fibrils from the cerebral and spinal ganglia are composed of flattened tubes made up of large oval cells, giving them a jointed appearance. Left in water for a while, and their contents then squeezed out, the latter is found to be more or less fluid, and have the appearance of a granular mass, presenting here and there soft globules and fine cells, some of which may be also adherent to the inner surface of the tube, and it may often be observed that they are situated between the thin layers of its walls. The embryological development of the nerve tubes is similar in all essential respects to that of the muscle tubes.

Structure of the Brain.—Baumgartner states that the brain consists of two tissues:—1. The proper cerebral substance made up of a layer of large and a layer of small cells, and which lie in a network. 2. The nervous fibrils entering into the ganglia, which cross each other in various ways, and, forming loops, return to the stem from which they departed. This structure has been detected in the brain of a chicken. The cortical substance in animals of a higher organization appears made up of a soft, membranous, adherent mass, and a network of vessels. Only a few loop-like nervous fibrils could be detected running back into the medullary substance. This medullary substance appears to be made up of fibrils and a special network in which they lie. The nervous fibrils are distributed at their termination in the brain as at their termination in the muscles. They are partly collected in bundles and partly form loops, which, uniting, crossing, or decussating with others, return to the point of entrance, and again join a main trunk.

Treatment of Angina Tonsillaris.—Baumgartner speaks of cauterization with nitrate of silver as the most effectual of all means when false membranes form. He has never lost a patient from this disease since he adopted this method of cure. Incision of the inflamed tonsil is another effectual means of relief.

Nature of Parasitoid Formations.—The same celebrated physiologist thinks that the formation of tubercle commences with the formation of simple granular bodies; that these cohere, and a globule is formed, and after that a granular cell, the process being, in fact, analogous to that exhibited in the development of the ovum. The caseous matter of tubercles consists of small granular bodies which are not widely dissimilar from the formative globules of the frog's ovum, such as they appear immediately after the formation of granules. If the caseous matter be in a more advanced stage of softening, it is found to consist almost altogether of globules, the cells containing a granule, their parietes being also somewhat granular. In proportion as the tubercular matter approaches the stage of suppuration, the granular bodies disappear, and the pus globules

having a cell contained in a cell, become more numerous and interspersed with transparent molecules. Tubercle appears to be a species of false membrane, and its formative process analogous in all respects to the formative process observed in the development of the ovum. The granular bodies are analogous to those of the yolk, which they resemble; out of them, as out of the latter, formative globules are developed, and then these latter change into cells. Here, however, analogy ceases. The cells of the healthy process unite together to form the different tissues; the pus cells remain in this low stage of development.

Wounds and Contusions of the Diaphragm from External Injury.—Mere contusions may occasion, says Mehliss, quoted in "The British and Foreign Medical Review," internal hemorrhage or inflammation, and eventual gangrene of the organ. Penetrating wounds are, however, for the most part of a much graver character. When their locality and size are such as to admit of speedy cicatrization, they are, so far as they are alone concerned, seldom productive of much mischief. In the opposite event either they cicatrize imperfectly, and eventually give rise to diaphragmatic hernia, or else they remain permanently open, affording to a greater or smaller amount of abdominal viscera a free passage into the thorax. The consequences are permanent disturbance to the thoracic organs, and, sooner or later, fatal asphyxia. This prolapsus is more frequent when the left side of the diaphragm is wounded; on the right side the liver opposes a decided obstacle to such a consummation.

Liebig's Soup.—When one pound of lean beef, free of fat, and separated from the bones—in the finely chopped state in which it is used for beef sausages or mince meat—is uniformly mixed with its own weight of cold water, slowly heated to boiling, and the liquid, after boiling briskly for a minute or two, is strained through a towel, from the coagulated albumen, and the fibrine now become hard and horny, we obtain an equal weight of the most aromatic soup of such strength as cannot be obtained even by boiling for hours from a piece of flesh. When mixed with salt and the other usual additions by which soup is usually seasoned, and tinged somewhat darker by means of roasted onions or burnt sugar, it forms the very best soup which can in any way be prepared from a pound of meat.

Post-mortem Contractility of the Muscles.—Dr. Bennet Dowler, New York, in his "Researches," mentions the following singular case:—A young man, twenty-five years of age, died; two hours after death, when the arm was extended to an angle of 45° from the trunk, and was struck with the hand, or, still better, with the side of the hatchet, he carried his hand to his epigastrium; but when the arm was extended upon the floor so as to form a right angle with the body, he slapped himself upon the mouth and nose. The contractility began to decline in the third hour; and by the fourth hour all motions of the limbs ceased, though the pectoral muscles assumed the ridgy or lumpy form when percussed. An hour after death the thigh was moderately contractile. The left heel hung down near the floor; its flexors, after being struck, drew up the heel against the buttock. Five hours after death the contractility had ceased and rigidity prevailed. It is remarkable that in all the cases mentioned the heat of the body remained at a very high standard for some time after death, and in some instances even rose after the cessation of respiration. In the case above, the heat was far above the usual standard of health for seven hours, only sinking in that time from 111° to 102°.

Popliteal Aneurism Cured by Compression in four days.—The case is related in the "Dublin Quarterly;" it is that of a man, thirty years of age, admitted in Steven's Hospital, under Mr. Cusack, with a pulsating tumour, of a fusiform shape, in the right popliteal space, possessing unequivocally the characters of an aneurism. In its long axis the tumour measures three inches; its centre, the broadest portion, extends across from the external to the internal hamstrings. Pressure on any point of the femoral artery

arrests the pulsation in the tumour; a very small amount suffices to accomplish this when exercised upon the vessel as it crosses the pubis. The pulsations are strong, equable, and synchronous with the ventricular systole. No *frémissement* is perceptible to the hand placed over the tumour, nor is any *bruit de soufflet* audible by the stethoscope. The parietics of the aneurismal sack feel solid, and cannot be compressed so as to empty it of its contents. The collateral branches above the knee are very large; one in particular, which crosses the internal condyle, is fully equal in size to the radial artery. Trifling pain after walking; no abnormal indications in the region of the heart. Two months before his admission, while walking, he felt something suddenly give way, attended by a throbbing sensation and slight pain. Upon examination, he discovered a pulsating tumour, the size of a pigeon's egg, and the foot for a short time was cold and numb. The swelling gradually increased. The patient was ordered ten drops of tincture of digitalis three times a day, and to rest in the horizontal position. Readie's pelvic ball-and-socket apparatus was applied on the patient, and the pad adjusted so as to bear perpendicularly upon the femoral artery, as it passes over the pubis. A degree of pressure was exercised sufficient only to diminish, without entirely interrupting, the current of the blood through the vessel. No congestion of the limb followed the application of this pressure, but shortly afterwards the temperature of the leg and foot fell considerably. The patient was able to bear pressure on the same point for four hours; when it became painful, by regulating the screw which connects the screw-pad with the curved arm of the instrument, the pad was capable of being shifted to a small extent. By thus alternating the pad upon the two points within a range of about one inch and a half, uninterrupted compression of the artery was maintained and a cure accomplished, without the aid of a second instrument.

Case of Enlargement of the Labial Glands.—A young man, twenty years of age, was admitted under the care of Mr. Wilde, surgeon to St. Mark's Hospital, having a remarkable enlargement of the upper lip, which began about two years before. It was not attended with pain. An operation was performed for its removal, and the diseased mass was carefully examined by Professor Aldridge. He stated that the portions of the upper lip were natural structures in a state of considerable hypertrophy. This increased nutrition appears not only to have affected the reticular cellular tissue of the glands, but likewise the fibrous structure of the cutis; this being preserved with difficulty in its natural condition, healed kindly, and there has been no return of the disease.

Fibrous Tumours of the Uterus.—The most useful position, says Mr. Lee, for those tumours is the submucous, viz., those projecting into the cavity of the womb; and the pedicles of these are generally situated just below the openings of the Fallopian tubes. The next position in which they are most abundant is the posterior wall and fundus of the uterus; they are very rarely situated in the anterior wall, and still more rarely in the cervix uteri. These observations were obtained by the examination of seventy-four preparations in the museums of the Royal College of Surgeons, University College, Bartholomew's, Guy's, and King's College.

REVIEWS.

The Brain and its Physiology; a Critical Disquisition on the Methods of Determining the Relations subsisting between the Structure and Functions of the Encephalon. By DANIEL NOBLE, Member of the Royal College of Surgeons. 8vo. London: 1846. Pp. 450.

The subject of which this volume before us is an excellent embodiment has for a long time past

engaged much of the attention of the author; and, judging from the manner in which he has executed the task of its elucidation, his inquiries have been most ably and agreeably prosecuted.

The leading object of Mr. Noble in bringing together the facts and inferences contained in this work is to show, by a process of inductive reasoning, how intimate, if not essential, is the relation which holds between cerebral development and intellectual faculty. Without taking the side of phrenology, properly so called, we must do our author the justice to say that he has brought together a vast mass of evidence,—some known aforesaid, and other new,—and that from such evidence he has drawn inferences which can scarcely be objected against by any lover of legitimate logic. The only question against the induction will rest upon the amount of facts which are taken for its authority—an amount scarcely sufficient, we should say, to justify sweeping conclusions, and the constitution of generalities, and yet enough to incline the lover of phrenology to feel confidence in the soundness of his suppositions. Mr. Noble has availed himself of no doubtful data, and has certainly not pushed conclusions further than a laudable energy in the performance of his task would account for; and whilst, on the one hand, the pure anatomist or physiologist will thank him for his able exposition of the structure and general functions of the brain, the phrenologists will, to a man, hail him as one of the most temperate and logical of the annotators of their science.

The following observations on the much-agitated question of the size and function of the posterior lobes of the brain in the inferior animals is an excellent specimen of our author's style, and of his clear and explicit way of meeting counter-statements:—

"When anatomists set forth that the posterior lobe is relatively small in the inferior animals, and found this assertion upon the fact that the hemispheres of the brain do not extend backwards so as to overlap the cerebellum in the same way as they do in man, they should have some regard to the circumstance of their bodies being in the horizontal position, which demands such an accommodation of the cranium as shall fit them for it; the *foramen magnum* of the occipital bone is unavoidably placed further back in these creatures, than it is in the human subject; and this modification places the cerebellum, of course, rather behind than under the cerebrum. A moment's reflection upon this matter will render it clear enough. The actual size, however, of the posterior lobe of the brain cannot be affected by the mere circumstance of its relative position. There is also another point for consideration, in connection with this subject: what is to determine the line of the posterior lobe anteriorly? How is it to be settled where the posterior lobe ends, and where the middle begins? In estimating the development of any division of the cerebrum, it surely cannot be just to regard but one of its boundaries. The fact is, in discussing such questions as these, physiologically, we gain no advantage by the simple aid of mechanical data; we must go to *function*, in order to make out correlative parts. In this view of the case, it must be remembered that the brain of man possesses several portions which the inferior animals want, correspondently with the possession of other and more exalted faculties of the mind. It must be recollected, also, that those superadded structures are constituted of certain convolutions, situated, for the most part, in the superior region of the cerebrum, just above and behind the anterior lobe; the necessary consequence of which state of things is, to supply the true posterior lobe with a comparatively backward locality.

"Let any one take up the brain of a sheep, and compare it with that of man; he will, in the latter case, notice several transverse convolutions superiorly, which are completely absent in the former. If the analogy of the respective structures be made a matter of study, it may be seen that certain longitudinal convolutions

which, in the human brain, belong to what is called the posterior lobe, in the sheep, run into what some may be pleased to call the middle lobe; and this circumstance arises from the absence of parts in the one instance which are found to be present in the other. It should be always kept in mind, that the anatomical divisions into the middle and posterior lobe are quite arbitrary, and, as ordinarily formed, have no physiological basis. The author has referred to the sheep's brain as the subject for comparison with the human structure, not because it constitutes any exceptional case, but on account of its ready accessibility. As may be gathered from many of the statements that have preceded, a like principle pervades the brain and nervous system throughout the whole scale of animal organization." (Pp. 316—318.)

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsman or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein Carfax, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

Crassus.—The paper on "Fracture of the Base of the Skull" has been received, and will obtain an early insertion.

Mr. Jamieson.—The lesion is not uncommon, but the symptoms of its existence are often very obscure. The diagnosis is in all probability correct.

M. D., Edinburgh.—The Apothecaries' license must be procured, or there is danger of prosecution for illegal practice.

Mr. G. L. Simpkins.—We have been informed of the proceedings of the parties, and there is no doubt their impositions will be speedily exposed and punished.

A. B., Dublin.—The newspaper was duly received.

Scotus.—Ether has been employed in some cases of traumatic tetanus with decided success, according to the testimony of those who are worthy of credence. There has not been sufficient experience, however, to warrant the conclusion that it will always succeed.

L. L., Basingbourne.—Celsus is a good Latin author, and not difficult to translate. The secretary of the Apothecaries' Society is the most proper person to be consulted in reference to the other parts of the letter.

Tyro.—Ether has been exhibited to patients during labour without any injurious effects being produced on the fetus.

Tenby.—The debt can be recovered in the County Court with but little expense. A physician's fee is considered honorary, and is not recoverable at law.

Mr. W. Thomas.—Creosote combines in all proportions with alcohol, ether, and naphtha. It is highly antiseptic; it is employed in toothache, ulcers, and cutaneous diseases externally, and to check hemorrhage; and internally as a stimulant, and for the prevention of nausea and vomiting. Its powers have been greatly overrated. It is injurious in inflammatory conditions, and structural diseases of the stomach, and frequently fails in allaying the sickness dependent on organic diseases—as of the heart and kidneys. The Ung. Creosoti of the "Pharmacopœia" is used in cases of ringworm, &c.

Chirurgus.—Iodide of potassium has been employed with success in cases of hemiplegia. The dose is about 10 grains a day at first, gradually and cautiously increased.

J. B.—The paper is inadmissible.

M.R.C.S. and L.A.C., Manchester.—A radical cure may be accomplished; it is, however, inadmissible if the testis is diseased, or if the hydrocele is complicated with irreducible hernia, or if the tunica vaginalis preserves its communication with the abdomen.

—, Aug. 3.—The party may be prosecuted by the Apothecaries' Society if he should visit and dispense medicines with a license.

C. E. V. G. informs us that he has received a letter from the Secretary of the National Friendly Society, Red Lion-street, London, offering him the situation of district surgeon. Their scale, he says, is liberal, but one clause in their regulations he does not like—that every medical officer elected shall be required to have an interest in the society by himself assuring for not less than £100. He wishes us to inform him in reference to the existence and prospects of the society. We are not able to give our correspondent the information he seeks.

Mr. W. W. Lloyd, Islington, near Birmingham.—It must have arisen from some oversight of the clerks. We were not aware of it.

Inquis.—Franklin communicated his observations in a series of letters to his friend Collinson, and explained in a satisfactory manner the phenomenon of the Leyden phial.

Miles.—We sympathize with our correspondent, and hope that the efforts of the profession to remove the degrading duties will be successful.

B. A., Walworth.—Special certificates would be necessary. The Medical Times Almanac will give the required information. The secretary of the university ought to be consulted.

A Medical Witness. Before giving evidence at the inquest, a legal summons, according to the prescribed and printed form, should have been demanded, without this a *joa* cannot be obtained.

Magister. The *pay d* can be compelled to serve till of age, the indentures are then no longer binding.

George B.—The paper cannot be inserted on account of its length, and some repetitions on individuals, which it would not be prudent to publish.

A College Member is thanked for his kindness.

Mr. S. Johnson. A coroner may undoubtedly demand proof that a witness professing to be a medical man is so.

A Student of the Westminster Hospital.—The old apparatus, being the simplest, is the best.

An Old Subscriber.—The publication of the letter would not interest the profession generally.

Mr. G. Mansell.—We do not retain manuscripts after they have been used, unless required so to do. Communications not inserted are destroyed.

Medicus.—The preparation has been employed with decided success in the case mentioned.

A Member of the National Institute.—The information can best be obtained from Mr. Pass, the secretary.

* & c.—We are not aware of the nature of the inquiries referred to.

X. Y. X.—We believe the assurance company referred to is respectable.

Mr. J. B. Budgett, Medical Directory Office, 274, Strand, informs us that Dr. W. one is a surgeon of Edinburgh, 1836, and a physician of that university, 1839.

Mr. Southco, Camldridge.—The communication has been received in reference to the National Institute, but too late for insertion.

Letters and communications have also been received from Mr. W. W. Lloyd, Islington, near Birmingham; Inquis; Miles; B. A., Walworth; A Medical Witness; Magister; George B.; A College Member; Mr. S. Johnson; A Student of the Westminster Hospital; An Old Subscriber; Mr. G. Mansell; Medicus; A Member of the National Institute; X. Y. X.; Mr. J. B. Budgett, Medical Directory Office, 274, Strand; Mr. Southco, Camldridge; Crassus; Mr. Jamieson; M.D., Edinburgh; Mr. G. L. Simpson; A. R., Dublin; Scotus; L. L., Burslem, home Tyro, Treby; Mr. W. Thomas; Chirurgus; J. B., J.R.C.S. and L.A.C., Manchester, C.E.V.G.

THE MEDICAL TIMES.

SATURDAY, AUGUST 7, 1847.

THE INSTITUTE.

The annual meeting of the National Institute, to be held on Wednesday next, will be for the

profession an important event, to which we look forward with mingled feelings of hope and fear. Our distrust originates not with the Council, but with those whom they represent; and our hopes are founded in a sense of the merits which on one side claim recognition, and on the improved judgment which will most probably acknowledge them.

The Institute has undoubtedly been most useful: it has had hard work carved out for it, and has well performed it; it has disseminated useful information; it has inspired an *esprit du corps*, and it has diffused through the public mind an improved estimate of the capabilities and position of the general practitioner. We consider this much, but it has done more: it has frequently held close relationship with the Government, leaving impressions most useful for any future professional legislation. It has given the general practitioners a *locus standi*, a public embodiment, an actual legal existence—things most useful to them amid the negotiations and intrigues of the heads of the smaller classes of the profession. The defeat of the registration measure is a parliamentary victory we owe mainly to the National Institute. The retrospect, therefore, of the short year of its existence, is one of which the Council need not be ashamed; and, as we have said before, the only thing which makes us look with some small apprehension to the future fortunes of the Institute, is not the certainty of their merits, but of their professional appreciation.

We have had so many associations, baseless in their foundation and delusive in their management, that suspicion and distrust are qualities which naturally arise, and there are parties endowed with a fair share of activity who seem only to live to excite and diffuse those doubts and suspicions in reference to the National Institute. They would avenge the failure of many of their own impostures by ensuring the same ruin to an honest project. We trust, however, the increased and increasing discernment of even those who have been frequently misled will prevent any such invidious dissension in the present instance. We never wanted union more than now, and the body of general practitioners will not be true to themselves or to their own interests unless they extend a warm, generous, and general support to the only body which has either the inclination or the power to do the just public thing for them. We confess we should look with apprehension to the future of the profession if the National Institute were removed from the field; it is their presence alone that can secure us an equitable arbitration. Camillus-like, they can resist the aggressions of the Gothic invaders by throwing a sword into the scale; it is for us to see that they do not shun the ingratitude of that Camillus, nor we reap its deplorable results.

PROSPECT OF A REVIVAL OF BARBER-SURGEONS IN THE ARMY—CONDUCT OF THE GOVERNMENT AUTHORITIES AT THE HORSE GUARDS.

The position of the Surgeons of Great Britain and Ireland is at the present time very critical, from the attempts which are being made to impose on them the performance of duties which no persons with a due sense of their own respectability ought to undertake, and to compel them to accept the most beggarly rewards for their services. The medical officers of some poor law unions are urged to take the liberal sum of

34d. for each visit to a sick pauper, and to give him into the bargain all needful medicines. Navy surgeons are billeted next door to the cockpit on board ship, and their brethren of the army have been recently ordered to undertake the very responsible and respectable employment of branding all the deserters from her Majesty's service with the letter "D." The Government manifesto, which has been recently issued from the Horse Guards, is evidently a "new move," to check ambitious feelings, which, if allowed to freely develop themselves, might become so strong as to force even her Majesty's advisers to bestow upon deserving medical men becoming honours and substantial rewards.

It is a melancholy fact, that, with all the efforts that have been made for ameliorating the condition of our profession, we seem to be scarcely one step in advance. Sisyphus like, we have hitherto laboured in vain, and the period seems yet at a distance when we shall reap the reward of all our toils, and enjoy the full fruition of our most sanguine expectations. We learn a truth, however, from our present circumstances which ought never to be forgotten, that nothing less than public opinion, worked into shape and substance, strengthened and consolidated by union, can bring about the "golden age" of the profession. Statesmen and parliaments must be urged from without before they will exhibit symptoms of activity: they can never, and will never, take the lead; and we are now paying the penalty of former supineness and division. The medical community—acknowledged to be liberal, learned, and polite—is, nevertheless, yet experiencing social oppression, and, up to this day, social neglect, that have no parallel in the history of civilized Europe. In no other country have such attempts been made to cripple its energies, condemn its services, and lower its status; hence it is now encountering difficulties of such magnitude as require a vast amount of sacrifice and self-denial to effectually remove them.

In the outset of every struggle for the possession of just rights, it should be borne in mind that oftentimes the greatest discouragements are experienced. The tale of bricks is required without the usual gift of straw with which to make them; and it seems that, now the profession is roused to seek deliverance, there art taskmasters who would further humble it by imposing labours which are unprofessional and derogatory. In the army medical service the surgeon is to supersede the farrier in tattooing the deserter who is so unfortunate as to fall within the power of his military chieftains. The official document which has been very recently issued says, "that the Commander-in-Chief has, on the recommendation of a board of influential medical officers, to whom the subject has been referred, been pleased to direct that the method of marking with needles should be resorted to throughout the service, and that the operation of marking deserters shall henceforth always take place in the hospital, under the superintendence of a medical officer, who will be held responsible that the execution of the sentence is performed, the letter "D" being indelibly impressed on the skin."

It is a great pity the Commander-in-Chief had not been pleased to mention the names of those illustrious worthies upon whose recommendation pricking has become fashionable, that posterity might not forget the important act of which they are the authors, and that the unfortunate men upon whom the operation is performed might utter blessings upon them for superseding the cat by the needle. A pretty thing, forsooth,

for army surgeons to be reduced to the rank of infantry drummers and cavalry farriers, as they certainly are by the Horse Guards' edict—the one, up to the present time, having been “whippers-in” and the other “prickers-in” of the different regiments. As the operation has now become a surgical one, it ought to be made as important as possible; and, were it not for the additional suffering it would entail on the men, we would recommend that the name of the Commander-in-Chief of the Army should be neatly imprinted around the capital “D.”

The surgeons, we find, are made “responsible” that the execution of the sentence is effectually performed. Of course, at first, the authorities must be lenient, as the operators, not having experience in this new department of their profession, may not furnish the letter with all the attributes of immortality; and, as a consequence, commissions will be in danger of having the War-office “D” indelibly impressed upon them. The army medical officers require instruction in their new duty, as they are now perfect novices; and the Government must forthwith raise to the dignity of professor some farrier deeply skilled in the art of pricking, at whose feet university doctors and college members must attentively sit and receive instruction. For what purpose, we ask, is the responsibility of making an indelible mark in the flesh placed upon the surgeon, unless it be to degrade him? Is the operation one which requires the exercise of so much skill, and is fraught with so much danger, that none but educated gentlemen ought to perform it? *Proh pudor!* Would it not have been far better to have placed the surgeon in the drummer's place, that the strokes of the cat might be scientifically adjusted to the exigencies of the culprit's strength, than that he should be called to perform the silly act of marking a man's flesh with a letter, which any illiterate farrier or sailor could do, and embellish the engraving with a pretty mermaid into the bargain? Lashing a soldier's back with a whip, a surgeon's presence may be necessary to prevent the culprit from being flogged to death; but no such excuse can be made when he is doomed to undergo the operation of marking.

From tattooing to shaving there is but one step—the latter operation having quite as much respectability about it as the former; and we should not be surprised to hear of another new regulation being issued from the War-office, commanding all army surgeons to superintend the lathering and scraping of the officers' chins. By this the young ensigns and cornets of the crack regiments would be especially benefited, as it would remove many of the dangers attendant upon the first shave; while numbers of the older officers, whose hands are anything but steady in the morning, would find the surgeon's superintendence at the toilet a very proper addition to the comfort and respectability of British officers. We consider it, therefore, not very improbable, that her Majesty's Ministers will advise her to grant, without delay, a new charter to the very ancient corporation of Barber-Surgeons, by which the art and science of tattooing and shaving may be one and indivisible.

The new military regulation is a gratuitous affront offered to the whole medical profession, which it is bound to resent. The eyes of Europe are turned upon it, and the French medical press has stigmatized the circular memorandum as a revolting measure. The signs of the times must

be carefully noted, so that no opportunity may be lost of improving our social condition, and of transmitting to posterity an untarnished reputation.

THE INQUEST AT PUTNEY.

THE attention of the members of the profession continues to be directed to the late judicial proceedings in the coroner's court at Putney, touching the death of the young lady, Miss Sophia Dallett. We have received numerous letters from different medical gentlemen, and one from Mr. Farmer, the druggist, who received such a severe castigation from a contemporary, because he prescribed at the outset of the illness “a mild mercurial and aperient” for the patient. It is our duty, as public journalists, to hold the scales of justice with an even hand, and, while careful to maintain professional reputation, not to be unmindful of the interests of society.

parties in this unfortunate case whose conduct has been called in question—the medical gentleman who attended the patient in her illness, and the druggist who was accustomed to furnish the family with certain domestic medicines. The former has been freed from all blame in the treatment of the case by the coroner's jury, and the professional gentlemen who were called in at the last stage of the illness; the latter, while exonerated by the medical gentlemen, the family, and the jury, has been severely castigated by certain parties, and his conduct held up to public approbrium as strongly exemplifying the evils of amateur practice.

It seems that, when Dr. Cormack was first called to attend the patient, “she was labouring under severe abdominal pain, and distressing retching,” doubtless with much tenderness over that region where pain was felt. To relieve these distressing symptoms opium was prescribed, without, however, any beneficial results. The patient afterwards became comatose, which, being mistaken for narcotism, an emetic and the stomach-pump were used, and the patient shortly afterwards expired. The professional attendants of the deceased can best understand how it was that there had been no local abstraction of blood, &c., usually considered so necessary, though the pulse may indicate great prostration of strength, and why opiates and brandy were ordered when the inflammation was raging in all its intensity. It is to be lamented that the patient should have been subjected to the action of an emetic, to the thrusting of a stomach-pump down her throat, and to the shaking and slapping which are considered so necessary when opium is exerting its influence on the constitution; for, during these attempts to rouse her from her slumbers, she sunk into a “sleep that knows no waking.”

We are fully convinced, from a review of the evidence, that Mr. Farmer, the druggist, is not chargeable with exciting a fatal inflammation by the drugs which he gave when the patient first felt unwell. We are of the number of those who would strongly condemn the tampering with human life by druggists and quacks, and our best efforts shall always be employed to bring about the total annihilation of the latter, and to confine the former to the legitimate exercise of their trade. This is not to be accomplished by falsely charging individuals with crimes of which they are entirely innocent; but by constantly setting before the public “the truth, the whole truth, and nothing but the truth.” Mr. Farmer

complains that the medical journal referred to has stated things at variance with the truth, in many important particulars, and that the report, as a whole, is garbled, incomplete, and partial. And is this the way by which the profession is to attain a proper standing with the public, and by which druggists' counter practice is to be put down? We think not: for the community has too long entertained an opinion that, when Demetrius and his workmen cry “Great is Diana of the Ephesians,” it is only because their craft is in danger. Mr. Farmer tells us that Dr. Cormack, though a physician, is the proprietor of a chemist's shop, as like his own in appearance and objects as it is possible to render it, and he ventures to assert that if any one had gone to that shop before the melancholy occurrence, and had asked the assistant to supply medicine for a person labouring under a supposed bilious attack, that drugs of a similar description to those supplied by himself to the deceased would have been handed over the counter with as little hesitation and, perhaps, in exchange for as few pence. Here, then, we find the physician charged with the vending of drugs and chemicals in the same way, and upon the same terms, as the druggist; and the latter asks any one to be good enough to point out to him why a mild mercurial and an equally mild aperient, coming from one shop, should be set down as rank poison, and as “razors placed in the hands of suicides,” whilst out of another, only about two or three hundred yards distant, the same drugs should be deemed efficient and proper remedies for disease? Here, then, the physician, or his assistant, is as much to blame in prescribing chloroform for disease as the druggist, and quite as likely to fall into error. If medical gentlemen think proper to keep shops, they ought to be especially careful not to “flirt” with sickness in a shopkeeping spirit. It is nothing less than rank quackery to prescribe for disease at a venture; and, if legitimate practitioners do this, who can wonder that the hosts of unprofessionals who dabble in physic should follow so injurious an example? Mr. Farmer takes for his *Magnus Apollo* his neighbour, Dr. Cormack; and as salts, senna, blue pill, and colocyath are dispensed at the one shop for the sterling coin of the realm, he does not see why the same exchange of commodities should not take place at the other. Moreover, Mr. Farmer considers that his giving two purges of salts and senna, “as sharp as a razor in the hands of a suicide,” when there was impending ulceration of the intestine, is no more open to severe strictures than an aperient mixture still in the possession of Mr. Dallett, prescribed for, and sent to be taken by, the deceased on the very morning which closed her existence.”

Mr. Farmer, in vindication of himself, refers to the medical evidence at the inquest. Dr. Cormack said that he did not convey, nor did he wish to convey, the idea that the disease arose from the improper administration of medicines in the first instance; Dr. Wane declared that he did not consider them dangerous, or in any way hurtful to the deceased, and certainly were not such as were calculated to hasten the result; while Mr. Charles Shillito added his testimony, that the medicines supplied in the first instance had nothing to do with the death of the patient.

Medical journalists, in advocating the rights of the profession, should be particularly careful not to go beyond the truth. Those who do this are stumbling-blocks in the way of sound Medical Reform, and little better than enemies in the

camp. The public sympathized with Dr. Cronin from this very circumstance, and viewed him as an individual unjustly persecuted. In the present instance the garbled and one-sided statement, in reference to Mr. Farmer, will fail to produce in the public mind that disgust with unlawful practitioners which will help the members of the profession most materially in putting them down. Clad in the armour of truth, every arrow shot against us shall fall without injuring, and a victory over every enemy shall eventually be obtained.

GLYCERINE.

In another part of our paper appears a communication furnished to us, at our request, by Mr. Startin, on the medicinal uses of glycerine—the sweet principle of oils.

It will be recollected by our readers that the first account of the use of this liquid as a medical agent was contained in the pages of this journal some eighteen months ago, when Mr. Startin's Practical (and, therefore, valuable) Lectures on Diseases of the Skin were in the course of publication.

We believe the letter in the present number to which we have made allusion contains the most complete information on the subject of this new therapeutic which has yet been made public; and we, therefore, gladly insert it, in answer to the numerous inquiries we have received on the subject.

THE BOROUGH OF STOKE-UPON-TRENT.

Mr. T. Piers Healey, a gentleman known to most of our readers from his connection with this journal and with legal medicine generally, having received a very strong invitation, was announced as a candidate to the electors of Stoke-upon-Trent on the day before the nomination (Tuesday, July 27).

On that day he addressed eight large meetings, at which there attended many thousands of the inhabitants. The general effect of these speeches may be best inferred from the reports of the *Staffordshire Advertiser*, which, speaking of the address at Langton, says "Mr. Healey's speech was well calculated to tell on a popular audience, containing passages of eloquent declamation, as well as witty and humorous illustration."

Mr. Healey's opponents were the well-known Alderman Copeland and Mr. J. Lewis Ricardo; and the Alderman, having been understood to have abandoned his old political predilections for those of Mr. Ricardo, both these gentlemen obtained a united support of the two parties formerly opposing each other, viz.—the Liberal and Conservative. This conjunction of opposite parties was, of course, most adverse to the interests of Mr. Healey whose friends, from the shortness of the time found it impossible to make head against this unexpected combination.

At the nomination, however, the popular voice declared itself very decidedly against this coalition. Mr. Alderman Copeland was unable to show himself on the hustings; Mr. Ricardo met with a most unfavourable reception; while Mr. Healey's speech, lasting for one hour and half, was heard with breathless silence, the speaker himself being received with warm emotion and enthusiastic cheering by a multitude consisting of not less than from twelve to fifteen thousand persons.

When a show of hands was called for, very few were raised for Alderman Copeland; some more for Mr. Ricardo; and, to use the words of the *Staffordshire Mercury*, "a perfect forest for Mr. Healey." About thirteen hundred voters polled. Of these Mr. Healey had three hundred and eighty-one, which, in consequence of the combination, was of course a minority.

Several cases of bribery, however, being made out, it is understood that a petition will be presented against Alderman Copeland's return, which will probably result in Mr. Healey's being seated for the borough.

As the expenses of this petition will be borne by the electors of the borough, some gentlemen interested in medical politics have already proffered contributions in support of the undertaking. Mr. Williams, the solicitor, of Hanley, will be the gentleman through whom the petition will be prepared.

After the close of the poll, many influential electors, including some of the most active members of Mr. Ricardo's committee, waited on Mr. Healey to express their regret at a result arising from temporary confusion in the state of parties, to invite Mr. Healey to stand on the next vacancy, and to assure him of their united support. A proposition was immediately set on foot for a public dinner, to which Mr. Healey is to be invited, and several of the operatives have since commenced a subscription to present the rising candidate with one of the best specimens of their local manufacture.

"PROGRESS" IN FINSBURY.

Mr. Wakley and Mr. Duncombe have walked quietly over the Finsbury course. Mr. Duncombe stayed at home on the nomination day; and it would have been well for Wakley's reputation if he had followed the example of his colleague. We do not remember, in the whole course of our experience, to have read even an election speech so full of vulgar impertinence as that with which the coroner of Middlesex insulted the understandings of the electors of Finsbury. Election speeches are seldom very famous for refinement and good taste. It is necessary sometimes to deal in claptraps and to use strong language in deference to the gross appetites of a mob; but Mr. Wakley seems to have delivered himself of his vulgarity, not in deference to the tastes of his audience, but out of a natural love for the thing itself. He absolutely revelled in the development of his low grovelling views and opinions, and exhibited, in a most unmistakable aspect, to the world all the worst characteristics of an incurably vulgar mind.

Mr. Wakley's contempt of literature is well known. He will go down to posterity as the man who declared, in the House of Commons, that he could write such poetry as Wordsworth's by the mile. He seems to measure men by the standard of the apothecary's shop. On the hustings, the other day, he spoke with supremest contempt of Mr. Samuel Warren, as a man who, "he would be bound to say, did not know a dose of salts from a dose of rhubarb." There had been some talk of Mr. Warren coming forward to contest the representation of Finsbury. Now, Mr. Warren is an author and a man of genius. We have no sympathy with his political leanings; but we cannot deny his claims to be considered as a writer of great power and versatility. Now, Mr. Wakley thinking, on Wednesday last, that it was his bounden duty to insult even a rumoured candidate for the suffrages of the good people of Finsbury, and being at no trouble to find the vulnerable point of Mr. Warren's public character, came down upon him without any misgivings as to the effect of his denunciations. He called Mr. Warren an author. He pilloried him at once as a man of letters. He held him up to scorn as "a sort of writer for the magazines;" and, thinking he had done the thing handsomely, smiled significantly at the people, as though he would say, "I think that we had him there;" and then went on to ask why, if Mr. Warren must write, he does not write about law? Now, as Mr. Warren has recently been writing, and very successfully, about the law, one would think that the object of this question was the exposure of Mr. Wakley's own ignorance; but we can assure the member for Finsbury that he need not take any trouble to supply us with additional evidence on that head, as we are perfectly satisfied of the fact with-

out any further proof than we have long had in our possession.

We need not trouble ourselves with any observations on that part of Mr. Wakley's speech which related to the absence of his colleague from the hustings on so memorable a day. The excuse was either pure matter of fact, or it was an egregious lie. We shall not pause to inquire which hypothesis is the more colourable. We are now only referring to that portion of the harangue which is to be stigmatized as an offence to the intelligence of Great Britain. Mr. Wakley's systematic contempt of all intellectual greatness—the source of those "intellectual joys" which, it is well observed by a morning contemporary (the *Herald*), "are at once the solace and the safeguard of his more fortunate fellow-countrymen," shows how far he lags in the rear of the enlightenment and liberality of the age. He talks of liberality, but is the most illiberal of men; of progress, and he is a mere sluggard. There is not an artisan in Finsbury who is not far in advance of him. Are these the men to prate about liberality and progress? Are these the men to represent the growing civilization of this great empire? When, years ago, in an emphatic appeal to the intelligence of England, Shelley, exhorting the people to patience and forbearance, exclaimed—

"Science and poetry and thought
Are thy lamps; they make the lot
Of the dwellers in a cot
So serene they curse it not;"

the measure of the people was well taken; but a quarter of a century later, a "liberal" orator would have taught them to despise those intellectual solaces which elevate the day labourer, in his humble cottage, to the level—nay, perhaps, above it—of the proudest peer in his palaced home. Mr. Wakley may be sure that the people of England are not to be insulted with impunity after this fashion. They know and appreciate the dignity of the literary character; they set a true value upon that without which they would be poor indeed. It is one—the greatest one of the boasts of the present age—that the highest intellectual pleasures are now within the reach of the poorest labourer. It is not only that the people have a literature of their own—but that the literature of the rich has now become also the literature of the poor; and that there are few so destitute and so desolate as to be denied the solace which Mr. Wakley laughs to scorn. A man of this intellectual calibre is sadly out of place as the representative of an intelligent constituency. Let the people of Finsbury ponder upon the manner in which he has insulted them. In the absence of all opposition, he has been returned for the Parliament now in course of construction. We could almost wish that the Parliament may be a short one, if only that it might run a chance of being purged of such impurities as those which, in the teeth of our own political leanings, have called forth from us these comments.—*Atlas*.

MEETING OF POOR-LAW MEDICAL OFFICERS.

A numerous and highly respectable meeting, convened by advertisement, of medical men connected with various unions in the midland counties, was held on Wednesday, July 28, at the Royal Hotel, Matlock, Bath, to take into consideration the subject of pauper medical relief. During the discussion which took place, and on which resolutions were founded, the most glaring absurdities of the present system were adduced. Many of the medical men were paid at a rate totally inadequate to the services performed by them, some being as low as 1s. 3d. per case, for which pittance they have to provide drugs, horse expenses, and a dispenser; the distance over which they have to travel in numerous instances was enormous; in other cases £5 for every thousand inhabitants were allowed. One gentleman had a union workhouse thrown in for nothing. An overseer's orders contained the following note:—"This patient is

to be attended in sickness, *but not in her confinement.*" A case in which a lad had compound fracture of both legs, the guardians refused to pay the medical man for more than one. Because another officer reduced a dislocation without medical order, he being then on attendance on the mother, he could not get his money from the board at all, though the commissioners were appealed to, and would have allowed the charge. Whenever the boards had been applied to for augmentation of salary, in consequence of excess of duties, the application was either rejected with the significant answer, "You can resign if you like, others are willing to doctor for the same price," or else a paltry pittance was given, as insulting as degrading. Our space will not allow us to enumerate all the astounding facts adduced at this meeting, and we sincerely hope other union officers will meet to represent to Government, fully and fairly, the injustice under which a class of men, the most useful in the state, labour. If a hundred patients in one district are paid for at the rate of 6s. 6d. per case, the lowest sum sanctioned by the commissioners, surely, in other districts 1s. 3d. is less than should be tolerated in any union. We consider this subject one of the greatest import to the community at large, and we express our firm conviction that boards of guardians are not the persons to be allowed to debase the profession and injure the poor. A Government medical inspector, acquainted with the value of general practice, should be appointed to fix the salaries upon a just and equitable footing, and correct the abuses which have crept into the system through a parsimonious policy. We would give liberal and efficient salaries, and provide in rural districts medical relief on a more extended basis, for, above the pauper, there are a class equally destitute in respect of procuring medical advice, and many hundreds are annually lost from this cause. Great praise is due to the promoters of this meeting, and we trust our columns may chronicle many more in other parts of the country.

ANSWER TO THE IRISH MEDICAL PROTEST FROM THE LORDS OF THE TREASURY.

Dublin Castle, July 26.

SIR,—I am directed by the Lord Lieutenant to state, that the memorial from physicians and surgeons, complaining of the rates of payment allowed under the temporary Fever Act, having been submitted to the Lords of the Treasury, their lordships are of opinion that the remuneration is as high as under the circumstances of the case they should be justified in granting.

I have the honour to be, Sir, your obedient servant,

J. W. REDINGTON.

J. W. Cusack, Esq., M.D.

THE INQUEST AT PUTNEY.

[To the Editor of the Medical Times.]

SIR,—As in my report of the inquest on Sophia Dallett, inserted in the last number of your journal, no mention whatever is made of Mr. Farmer, the chemist, who, in another report in another journal (*quite another journal*), is made to bear the entire onus of the case, it is due to you and your readers that, as the reporter, I should account for this omission. I must do so by the simple statement that at the adjourned inquest, which I reported, not a single allusion was made to Mr. Farmer; and, so far from the *onus probandi* resting with him, Dr. Cormack looked upon it as entirely his own, as did the coroner and the jury, and I should imagine every one else.

Certain prints, like certain persons, are incapable of slander; and, doubtless, Mr. Farmer will find solace in this fact, for the unmerited contumely (*to my certain knowledge*) that has been heaped upon him; but should he not be altogether satisfied with this, and will challenge a

professional jury, as Dr. Cormack challenged a jury of laymen, I will undertake the duty of his counsel, and guarantee him not only to come out scathless, but perhaps even with a little improved position.

I am, Sir,

Your obedient servant,

WILLIAM HENRY BROWN, M.D.

Belgrave House, Park-road, Old Kent-road, July 26.

THE LEGAL PRIVILEGES OF THE LICENTIATE OF THE HALL.

[To the Editor of the Medical Times.]

SIR,—Your correspondent O. L. U. is very needlessly perplexed respecting the legal rights of the licentiate of the Hall. He asks by what authority the licentiate of the Hall practises physic? I answer, by the authority of an act of Parliament, which overrides all charters, whether granted to Colleges of Physicians or Colleges of Surgeons.

The Act of 1815 empowers the court of examiners to examine candidates in the science and practice of medicine, and as to their fitness and qualification to practise as *apothecaries*, and also to grant licenses to approved candidates, "entitling them to practise as such in any part of England and Wales."

The licentiates of the Hall are, therefore, entitled by act of Parliament to practise as *apothecaries*. Let us see what is the kind of practice thus limited to those who have passed the Hall examination. At the time of the passing the act, the apothecary was the ordinary attendant of the sick, officiating, more especially in country places, as physician, surgeon, and accoucheur, while, at the same time, he supplied all medicines and medical and surgical appliances which might be required by his patients. This cannot be denied. The number of members of the College of Surgeons was at that time very small, and smaller still, perhaps, the number of doctors of medicine. The population of this country must, consequently, have been attended in medical, surgical, and obstetrical cases chiefly by the old apothecaries.

A license, therefore, under an act of Parliament "to practise as an apothecary" must confer a legal right to practise *physic, surgery, and midwifery*.

But the act contains a clause saving some of the privileges of the Colleges of Physicians and Surgeons.

Now, Mr. Lawrence, speaking on behalf of the College of Surgeons, denies that the diploma of a member confers any privileges at all. But, admitting that the diploma does confer privileges, it can be only since 1813 that those privileges extended beyond London and its suburbs. And I believe this extension remains still to be effected with respect to the privileges of the College of Physicians. And, then, the fact that doctors of medicine of any university are officially recognised as "physicians," whether they be or be not connected with the College of Physicians, as well as that many others than members of the College of Surgeons are officially recognised as "surgeons," proves that these collegiate *privileges*, so called, are not *exclusive* ones, and, therefore, the clause in the Act of 1815 referring to the colleges can only mean that there is nothing contained in the act to prevent a M.R.C.S. from practising as a pure surgeon, or a M.R.C.P. from practising as a pure physician, while the whole act manifestly entitles the licentiate of the Hall to practise any and every branch.

I wish it to be understood that in the above observations I have not said a word as to the *competency* of the licentiate to practise. Competency is one thing, and a legal right to practise is another. There can be little doubt, however, that most of the licentiates have availed themselves of the opportunities to study special surgery, necessarily thrown in their way while completing the *curriculum* for the Hall, in addition to such parts of surgery as are inseparably connected

with anatomy, the study of which is enjoined, and in which they are examined. And it is to be regretted that the authorities at the Hall have not included special surgery in their *curriculum* and examination, which I believe they are entitled to do, as the act empowers them to require a "sufficient medical education;" and is not surgery a department of medicine? (a) As such a *curriculum* and such an examination are in the contemplation of the Council of the National Institute, it is much to be desired that their plans for the reorganization of the profession may be carried into effect.

I am, Sir, your most obedient servant,
SELSTYERTHEIDIGER.

Lincolnshire, Aug. 2.

[To the Editor of the Medical Times.]

SIR,—In that vile and slanderous publication, the *Lancet*, of this week, is a letter abusing me for petitioning against that stupid bill of Tom Wakley's, and stating that I am in practice along with several others; which I acknowledge, and what of that? If I was to qualify, would the Apothecaries' Hall put me in a better position? I say no. Then why should I spend my money? I can now afford to charge lower than the regular doctors, and I do more business than any two of them; and I know the company will not prosecute me. As I don't give much credit, as I charge low, and I can make all over to my wife if they do; besides, there is more than twenty others in this neighbourhood who does the same. And I am at the hospitals to learn all I can, so that I think it is very hard to expose me; but it is all spite of the other medical men, and I hope you will put this in your paper this week, to show that I am not afraid of them, and that you will see me righted, as I take your independent paper in, and hate the meddling fool, Thom. Wakley.

Yours, very obediently,

J. ROLPHE, Surgeon; but not an Apothecary.
Paradise-row, Bethnal green.

GOSSIP OF THE WEEK.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma of this college, were admitted members on Friday evening, the 23rd instant, viz.:—Messrs. Charles Peter Markus, Ceylon; William Henry Ackland, Bideford, Devon; William James Blyth, Abergavenny, Monmouthshire; Henry Turner, Dorsetshire; James Lewis Holloway, Charlbury, Oxfordshire; John Owen Evans, Stoke Newington; Charles Astley Walters, Stockport; Alexander Henry Paterson, Stourbridge, Worcestershire; Joseph Adolphus, Kingston, Jamaica; Joseph Holmes Buxton, Bishop's Auckland, Durham; and William Home Popham, Judd-street, Brunswick-square.—On the 26th inst.—viz., Messrs. William George McClure, Newtownbreda, Belfast; John Lane Cutcliffe, South Molton, North Devon; William James Williams, London; Thomas Sympton, Lincoln; James Frederick Knipe, Cheltenham; John James, St. Just, in Penwith, Cornwall; Edward Bunbury Passmore, Lyncombe, Bath; William Mackey Ogilvie, Boughton Blean, near Faversham, Kent; Francis Henry Blaxall, Clacton, Suffolk; Richard Davison Miles, Watford, Herts; and William Braithwaite, Plymouth, Devon.—On the 29th inst., viz., Messrs. Mitchell Henry, Woodland, near Manchester; William Thomas Gaye, Minchhead, Somersetshire; Edward John ap Ellis Eytton, Overton, Flintshire; George Robert Hambury, Hereford; Alfred Mathias, Lamphrey Court, near Pembroke.

(a) At any rate, all surgeons claim to be considered members of the medical profession. If they are rightly so, it can only be because surgery is to be regarded as a *branch* of medicine; and, as every whole must include all its parts, so it must be held that a *sufficient medical education* ought to include surgery.

South Wales; James Edmund Clutterbuck, Newark-park, Gloucestershire; Francis Leopold Hooper, Great Canfield vicarage, Essex; Charles Jennings, Cheapside; Thomas Robinson, Leicester; and Horatio Carro Brenchley, Maidstone, Kent.

ROYAL COLLEGE OF PHYSICIANS.—The following gentlemen have been elected "fellows" of this institution, viz.:—Sir George Maerath, Knight, Plymouth; Henry Beaumont Leeson, M.D., Greenwich; Thomas Southwood Smith, M.D., Finsbury-square; Peter Nugent Kingston, M.D., Curzon-street, May-fair; and John Taylor, M.D.

APOTHECARIES' HALL.—Gentlemen admitted members July 22: John White Bridgman, and Robert Baker.—July 29: James Herbert Budd, Henry Bate, William Brook Charles Maxwell, Hugh Hastings, and Edward McDonnell.

QUEEN'S COLLEGE, BIRMINGHAM.—A special meeting of the council and friends of the college was held on Wednesday last, to vote a loyal and dutiful address to her Majesty on the occasion of the grant by her Majesty of a supplemental charter. The chair was occupied by the Right Hon. Lord Lyttelton, the principal. Letters expressive of regret at unavoidable absence were received from Earl Howe, the Lord Bishop of Worcester, and the High Sheriff for the county. Amongst the numerous friends present were —the Mayor (Mr. Robert Martineau), the Treasurer of the College (Mr. J. E. Piercy), the Dean of the Faculty (Mr. William Sands Cox), Professor Dr. Eccles, Professor Dr. Birt Davies, Professor Dr. Wright, Professor G. B. Knowles, Professor S. Berry, Mr. Alderman Room, Mr. T. Uphill, Mr. James Bourne, Mr. W. H. Osborne, Mr. G. Taylor, Mr. J. Suckling, and other friends.

Robert Bentley, Esq., M.R.C.S., of King's College, has been appointed to the chair of Botany, in the Medical School of the London Hospital, vacant by the death of Edwin J. Quekett, Esq.

The Provincial Association has been holding its annual meeting on Wednesday and Thursday. We regret to hear that the attendance has been scanty, the interest of the proceedings small, and the financial future of the institution itself anything but promising. The deficiency of the benevolent fund especially is most marked, and leads to much general dissatisfaction. We shall notice the proceedings more at length in our next number.

A CHILD POISONED BY LAUDANUM.—On Wednesday afternoon last, an infant, three weeks old, named Mary Ann Barlow, the daughter of Robert Barlow, 19, Ludgate-hill, was seized with convulsions, and, in order to give it relief, two drops of laudanum were mingled with a teaspoonful of gin and a rather larger quantity of water, and about two-thirds of the mixture were given to the child. She at first appeared to be easier, and slept quietly for about an hour, but at the end of that time was again seized with convulsions, and became so much worse that she was taken by her mother to a neighbouring druggist, by whom she was treated, but without effect, as she died on Thursday morning. An inquest was held upon the body, before Mr. Chapman, the borough coroner, at the Greyhound Inn, Baptist-street, on Friday last, when Mr. G. Smith, assistant to Mr. McGill, druggist, Rochdale-road, stated that the death of the infant was caused by an over-dose of laudanum; indeed, a single drop would be sufficient to cause the death of so young a child. The jury returned a verdict that "The deceased came by her death through an over-dose of laudanum, administered by mistake."

NEW FARINACEOUS PLANT DISCOVERED IN ALGERIA.—In Algiers a vegetable production has been found on the tops of mountains toward the south, and in Algeria Zaara, during the last campaign. General Jusuf has drawn the attention of Government to it. It appears like a lichen spread over a large part of Zaara. As for its identity, it is the *Lichen esculentus* which the Tartars use. They feed their beasts upon it, and

make for the poor a sort of bread; they consider it like manna sent by Providence. General Jusuf has had two loaves made of this lichen: the one, entirely of it, was more brittle and less consistent than the other, which had about one-tenth of flour in it. This loaf resembled store-bread, and had the flavour of it. The nutritious quality of this bread cannot be denied, when it is known that the distinguished chemist, M. Payen, has proved that an extract, similar to the starch formerly made by M. Berzelius, can be produced from it.

LONGEVITY OF A LUNATIC.—An insane person has recently died in Belgium at the advanced age of 109 years.

DISCOVERY OF ANCIENT REMAINS.—The railway excavators now engaged near the old Roman city, or "Isca Siluriana," known to moderns as Caerleon, in the neighbourhood of Newport, have dug out from their ancient graves, two massive coffins of stone, in which were found the remains of two human bodies, and in one an antique stone bottle, containing a thick liquid, upon which village practitioners in chemistry and medicine have not yet pronounced. The coffins resemble huge and rudely-fashioned troughs, with lids of stone almost as large as the coffins. From the fact that a stone coffin was found near the same place by excavators some time since, it is conjectured that the field was at one time used as a general burying-place for the inhabitants of Caerleon, whose boundaries, some five hundred years of ago, extended near to the spot where the coffins have been discovered.—*Globe*.

ABUSES OF ETHER.—On Monday, July 26, a young person called upon a dentist of the Palais Royal to have a tooth extracted. She was rendered unconscious by ether, and some hours after it was ascertained, by a medical examination, that her person had been violated. The dentist has been placed under arrest.

NAVAL APPOINTMENTS.—Deputy Inspector of Hospitals: E. Hilditch, to Bermuda Hospital. Deputy Medical Inspector of the Fleet: Dr. J. G. Stewart, to the *Vindictive*. Surgeons: T. H. Nation, to the *Imaum*, vice Cross; A. B. Cuxfield, to the *Pary*; J. Lambert, to the *Trincmalee*; W. Loney, to the *Amphitrite*.

The *Gazette d'Angsburg* contains a letter, dated "July 1st, on the borders of the Black Sea." It announces that travellers who came from Redont Kale, a fortnight past, report that the cholera is raging at Tiflis. More recent reports confirm this news; but the data of the intensity of this malady varies so much that it is impossible to say anything correct upon the subject.

REWARD OF MERIT.

The King of the Belgians wished to give a public testimony of his approbation of M. Orilla, for the numerous and eminent services he has rendered to medical science; he has, therefore, appointed him officer of the (civil) order of Leopold, by a resolution passed on the 20th of July. By a resolution of the same date, M. Heckerman, a senior of the medical faculty at Berlin, has been appointed chevalier of the same order.

M. le Docteur Fallot, a member of the Medical Academy of Belgium, and principal physician to the army, has just been promoted to the rank of officer of the order of Leopold; M. Cuvier, member of the same academy, and surgeon to the Ophthalmic Institution of Brussels, has been appointed chevalier: both of them for the eminent services they have rendered to science and the army, especially in the treatment of ophthalmic affections.

The bust of M. le Docteur Pariset, recently deceased, is to be executed in white marble, and placed in a conspicuous part of the Academy of Medicine, of which he was perpetual secretary.

M. Gervais, professor of zoology and comparative anatomy to the Scientific Faculty at Montpellier, and M. Dumas, professor to the Medical Faculty, both skilled in medicine and science, have been presented to the Minister of Public Instruction as candidates for the vacant chair. M. Gervais stands at the head of the list by the

Scientific Faculty, and M. Dumas is the first candidate of the Academical Council.

The Royal Academy of Medicine at Belgium has just been nominating the committee for the three years from 1847 to 1850. M. Vleminck has been re-elected president.

M. Fallot, principal physician of the garrison of Namur, and M. Verheyen, inspector of the *Service de Santé Vétérinaire*, have been elected vice-presidents. Dr. Marinus succeeds M. Lebeau, physician to the garrison at Brussels, in the capacity of assistant-secretary.

The Council of State has just come to an important decision concerning physicians called to fill municipal offices. M. le Docteur Guépin (of Nantes), appointed municipal adviser at the last election, saw his nomination cancelled by the Council of Prefecture, because of a disagreement between the officers of the municipal council and three of the professors of the College of Medicine. M. Guépin having appealed to the *Conseil d'Etat*, they came to the decision that the office of professor exercised by the physician did not rank among the public salaries. Consequently, it has annulled the decision of the Council of Prefecture of the Loire-Inférieure.

COPENHAGEN, July 19.—Lately, the Congress of Scandinavian Naturalists held its last session, which was honoured by the presence of the King. At this session it was announced that the congress would reassemble in July, 1850, at Stockholm. The King honoured M. le Baron de Berzelius with the dignity of the grand cross of Danebrog, to which dignity is attached the title of excellence. He conferred the honour of commander of the same order on M. Haasteen, of Christiania, Norway; and M. Nielson, of Lund, Sweden. MM. Ekstroem, Efner, and Reitzius (Swedes), and MM. Coriander and Faye (Norwegians), have obtained the cross of chevalier of Danebrog. The King has had a copy of the portrait of Thorwaldsen, by M. Horace Vernet; and his Majesty has presented it to the Society of Fine Arts at Copenhagen.

OBITUARY.—On the 26th ult., after a few hours' illness, William Penn Foster, surgeon, of Church-street, Stoke Newington, aged 44, beloved and respected by all who knew him.—Lately, at Waterford, Dr. Price, of fever, caught while in the discharge of his duties as physician to the dispensary.

MORTALITY TABLE.

For the Week ending Saturday, July 31, 1847.

Causes of Death.	Total.	Average of 5 Summers.
ALL CAUSES.....	964	940
SPECIFIED CAUSES...	962	935
Zymotic (or Epidemic, Endemic, and Contagious) Diseases.....	301	20
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable Seat.....	122	103
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	135	157
Diseases of the Lungs, and of the other Organs of Respiration.....	196	226
Diseases of the Heart and Blood-vessels.....	23	25
Diseases of the Stomach, Liver, and other organs of Digestion.....	82	94
Diseases of the Kidneys, &c.	13	8
Childbirth, Diseases of the Uterus, &c.	9	10
Rheumatism, Diseases of the Bones, Joints, &c. ...	9	7
Diseases of the Skin, Cellular Tissue, &c.	4	2
Old Age.....	33	50
Violence, Privation, Cold, and Intemperance.....	35	28

FOR A MORE SIMPLE ARRANGEMENT OF THE

MATERIA MEDICA,

BASED ON ITS PHARMACEUTICAL AND THERAPEUTICAL RELATIONS.

By GEORGE LEITH ROUPELL, M.D.

Cantab., F.R.S., Fellow of the Royal College of Physicians, Physician to St. Bartholomew's Hospital, Lecturer on Materia Medica at the College of St. Bartholomew's Hospital.

(Continued from p. 441.)

LECTURE V.

Proceeding with the list of crystalline alkaloids, I come to *Strychnia*, the active principle of the *nux vomica*. This is found in combination with another alkaloid, *brucia*, in the fruit and bark of several varieties of *strychnos*.

Strychnia is met with in brilliant transparent prisms or octahedrons; soluble in boiling rectified spirit; insoluble in ether; scarcely soluble in water—sufficiently so, however, to impart an intensely bitter taste to 80,000 times its bulk. The salts of *strychnia* are crystalline, and, from their greater solubility than the pure alkaloid, might advantageously be introduced into practice.

The symbol of *strychnia* is *St*, and its formula is $C^{24}H^{23}O^4N^2$. It acts upon the system as a tonic, as a powerful stimulant of the spinal chord, and as an antispasmodic.

The indications for its employment are—

1. Some forms of debility.
2. Paralysis of various kinds.
3. Some varieties of epilepsy.

Impaired powers of digestion, hemiplegia, and especially paraplegia, amaurosis, and paralysis of the bladder, are some of the disorders reliev-able by *strychnia*; and the fact of the bean of *St. Ignatius* having obtained great celebrity in Germany as a secret remedy for epilepsy would render the employment of *strychnia* in such cases deserving of trial.

It should be mentioned that the sexual with the other functions of the spinal chord have been found to be excited by this alkaloid. The dose of *strychnia* will vary with its object. As a tonic it should not exceed the $\frac{1}{30}$ th of a grain; as a stimulant, from the $\frac{1}{10}$ th to the $\frac{1}{8}$ th of a grain may be exhibited. Larger doses of commercial *strychnia* may, however, be given, as that usually contains *brucia*, in the proportion of one half. *Brucia* acts upon the system precisely as *strychnia*, though less powerfully, and is the cause of the red colour usually struck on the addition of nitric acid to the *strychnia* of our shops.

7. *Digitalis* is considered to be the active principle of the officinal plant *digitalis purpurea*, and is described as existing in the *digitalis laevigata*, *grandiflora*, and others. MM. Homolle and Quevenne, who claim the merit of discovering it, and have given directions for its preparation, speak of it as an extremely powerful agent,

100 times the strength of the dried leaf of *digitalis*, as having occasioned serious effects in the human subject in the dose of $\frac{1}{10}$ th of a grain, and as having destroyed life in a dog when the $\frac{1}{4}$ th of a grain was exhibited; they add that it is too powerful to be employed endermically. Its taste is acrid, its reaction alkaline, and its form crystalline. Further information, however, on this subject is still desirable, as other pharmacists have failed in procuring this principle in a pure and isolated form.

The effect produced by *digitalis* on the system is to increase the quantity of the urine, to check the frequency of the heart's action; but if its use be continued, or it be given in larger doses, it produces vomiting, distressing faintness, cold sweat, irregularity and feebleness of the pulse, coma, convulsions, and death. The chief indications for its employment are—

1. Some forms of dropsy.
2. Certain disorders of the heart and large vessels.

The forms of dropsy in which *digitalis* is most useful are hydrothorax, anasarca, and ascites, especially when dependent upon disease of the kidneys and heart. The disorder of the heart and arteries in which this remedy may beneficially be employed is irritability of their action, as well from mere functional disturbance as from organic structural lesion.

Digitalis is highly extolled by some practitioners in hemoptysis; and, from the volatility of its principles, will act in the form of vapour. Its officinal preparations are the powdered leaf, the infusion, the tincture, and the extract.

8. *Colchicum*, the active principle of the *colchicum autumnale*, appears in the form of colourless prisms or needles, soluble in water, acrid, and bitter to the taste.

The effect of *colchicum* or its active principle is that of a powerful local irritant, occasioning acute inflammation of the mucous membrane, with all its usual signs; it acts also as a sedative upon the nervous system, allaying pain and controlling certain forms of inflammatory action. *Colchicum* is said to increase the proportion of urea in the urine, as well as to augment the quantity of that secretion.

Adopting these views, the leading indications, then, for the exhibition of *colchicum* will

1. Local inflammation of a peculiar character.
2. Certain forms of neuralgia.

3. Deficiency of urea in the secretion from the kidney.

The peculiar form of local inflammation which *colchicum* is capable of relieving is, as is popularly known, the gouty. More question exists as to its efficacy in rheumatism. The action of *colchicum* in allaying pain would appear in some cases independent of its controlling vascular action, as relief to pain will result while the swelling remains. The property which *colchicum* is asserted to possess of increasing the proportion of urea would indicate the probability of this medicine in those forms of dropsy in which urea is notoriously deficient; and to his point my attention is at this time especially directed.

The seeds and bulb of the *colchicum* are officinal, the preparations of which are two extracts and a vinegar of the fresh cormus, a wine, and two tinctures. By regulating the dose the remote effects of *colchicum* may be produced, or with them may be combined the local action upon the mucous surface of the bowels.

9. Quina and 10. cinchona are the two last of the crystalline alkaloids mentioned in my list of the nitrogenized bases of officinal plants. Quina and cinchona are procured, as is generally known, from bark; the yellow yielding quina; the pale, or quilled, according to some botanists, the grey, according to others, yielding cinchona.

Quina ($C^{20}H^{24}O^3N$) crystallizes in fine silky needles, is soluble in strong alcohol and ether, and, to a certain extent, in water. Cin-

chona ($C^{20}H^{24}O^3N$) appears in large brilliant prisms, is soluble in strong alcohol, but insoluble in ether and in water.

Quina and cinchona resemble each other in many respects—in chemical reaction—in being themselves crystalline—in forming crystallizable salts with acids, and in their effects upon the system. The salts of quina, however, are almost exclusively employed in this country, and the disulphate is the only one which is officinal. This is met with in white, silky crystals, efflorescing on exposure to air, and of an intensely bitter taste. The disulphate of quina acts upon the muscular, the vascular, and the nervous systems. It gives tone to the muscles, strength to the pulse, and increases the appetite when given in moderate doses. Exhibited in large ones, it occasions sickness, headache, flushing of the face, feelings of fulness of the head, accom-

panied by loss of sight and hearing, numbness of the extremities, and delirium.

Quina is universally known to be a specific for ague, and for certain other affections which have a tendency to recur at definite and regular periods. It is a specific also for some forms of neuralgia; and some practitioners rely upon it as the best remedy for certain forms of acute inflammation. The indications, then, for the exhibition of the disulphate or other salts of quina will be—

1. Debility.
2. The tendency to periodicity in certain disorders.
3. Some sorts of neuralgia.
4. Certain inflammatory affections.

The character of the debility which quina is especially calculated to relieve is that produced by the simple exhaustion of the natural powers, unaccompanied by inflammation of the mucous membranes, or continued febrile action. In proportion as the secretions may be healthy, and the debility, in short, be simple, so may we anticipate advantage from this remedy.

Of periodical disorders, not only is ague cured by quina, but the numerous disorders which arise from marsh miasma, and which are, like it, characterized by paroxysmal recurrence. These need not be dwelt upon now; but it should be observed that where marked remissions take place quina is of essential service in very many occasions, and that where the disorder arises from malaria it should be exhibited, although the case should be complicated even with local inflammation, such local ailment being met by its appropriate treatment.

The form of neuralgia best relieved by the alkaloid now under consideration is that probably dependent upon the exhalation from unhealthy districts.

With regard to the exhibition of bark or quina in continued fever, in erysipelas, and even in the convalescence from these disorders, it is not by any means to be resorted to, as was formerly the case, indiscriminately. The treatment of acute rheumatism by quina in very large doses, from a scruple, for instance, to three drachms per day, is strongly advocated by some continental physicians. With us, however, the employment of quina in inflammatory diseases may be considered as limited to some forms of scarlet fever, and to the atonic periods of rheumatic affections.

Before concluding this subject, some notice must be taken of the difference in effect between bark and quina or cinchona. These alkaloids are essentially the febrifugal portion of bark, which possesses, besides other properties, such as astringency, tonicity and stomachic qualities. The employment of bark, therefore, should not be entirely superseded by quina; and it is deserving of mention that even as a febrifuge bark is stated to have been in some cases more successful than the mere quina.

It alone remains for me to add that quina is efficacious when used endermically, and that bark locally applied acts as an antiseptic.

The preparations of bark of the "Pharmacopæia" are the infusion and tincture of the pale, the tincture of the yellow; the powder, the extract, and the decoction of each of the three official varieties.

dictated by this view; case of epilepsy seemingly arising from gastro-intestinal disturbance; effects of various treatment upon it; supererrection of crissipelas; return of the epilepsy with severer symptoms; treatment; death; post-mortem appearances; observations; case of epilepsy chiefly characterized by debility; two other cases perhaps originating in gastro-intestinal disturbance; epilepsy consequent upon amenorrhæa; epilepsy ceasing after discharge of worms.

GENTLEMEN.—We have had several cases of epilepsy in the hospital of late. The present will be a favourable opportunity for their recapitulation with a few remarks.

Epilepsy is one of the most unsatisfactory and intractable diseases with which we have to contend. It often arises from causes which are as obscure as they are irremediable; and ours is then the melancholy office of variously ministering to the necessities of the sufferer, without diminishing the severity or lessening the number of them. These difficulties chiefly beset us in encountering the epilepsy of adults. Than this, there is no ordinary ailment more unmanageable. In the course of my practice I have treated very many cases of it, some of which have seemingly recovered, but truly speaking I could not say that medicines had much to do with the result. Others have improved for a time, and promised a permanent amendment, but, just as hope was at its highest, they suddenly relapsed and became worse than ever. In the majority, however, there has either been no approach at all towards improvement, or it has been so slow and insecure as to leave little room for rejoicing at the effects of drugs. From the personal observations I have been enabled to make, for some years past, in various public institutions, I am inclined to think that, if the truth were told, many similar testimonies to my own could be given to the almost incurable character of adult epilepsy. I do not say that such cases never completely recover—many of the milder of them undoubtedly do, but I think the process of cure is chiefly, if not altogether, Nature's: the worst cases are either persistent or fatal, despite the efforts of Nature or her ministers.

The epilepsy of early life is a less formidable ailment, because it often arises from circumstances which are capable of cure or of control, or which disappear spontaneously. When organic causes are in operation, the epileptic child is as much in jeopardy as the epileptic man; but when the convulsions are consequent upon irritation, itself not dangerous, or upon weakness from rapid growth or innutrition, there is rational ground to hope that recovery may be complete and permanent. The common saying, that a child may outlive its fits, bears reference to the constitutional change which we know to be connected with increase of years and of strength. Various causes tending to produce convulsions are operative in infancy and childhood, which either cease or are much mitigated with advancing age. Hence the reason that the epilepsy of early life is often lost in the adult.

Epilepsy is distinguished from all other ailments by the peculiar convulsions that characterize it. Usually at the moment of seizure the patient falls to the ground: this occasioned its earlier denomination, viz., *the falling sickness*. Whether he fall suddenly or slowly, the convulsions are the same, and consist of contortions or violent agitations of the body, which last from a few minutes to half an hour or more. The struggles are often excessive and accompanied with frightful distortions of the face; the eyes are fixed, and turned inwards or upwards, and the pupils generally contracted; the hands are spasmodically clinched, or incessantly grasping at some near object; the jaws are either fixed in spasm or the teeth gnash against each other, and frequently lacerate the lips or the protruding tongue; the breathing is heavy, oppressed, and irregular; the pulse quick, small, and hard; the lips often covered with foam. Whilst this state lasts, there is total insensibility. The convulsions having ceased, the patient either remains

for some time motionless, and seemingly asleep, and then slowly awakes up, or he partially recovers his intelligence at once, stares about him in ignorance of what has happened, and then commits himself to rest, completely exhausted or half stupefied.

The nature and duration of the attack vary considerably with different individuals. In strong robust people, the convulsive action is often so excessive as to require the best efforts of half a dozen attendants to restrain it; in delicate subjects, on the contrary, there is frequently only a sort of trembling of the whole body that is not difficult of subjugation. In other cases the spasms do not rapidly alternate with relaxations, but exhibit a sort of tonic or fixed character that gives to the seizure something of the appearance of tetanus. In others, again, there is great prostration at the commencement, and so little distortion or convulsion that the attack has sometimes been mistaken for a fainting fit. These differences have suggested a division of epilepsy into three species; but, with deference to the ingenious author of the distinctions, I cannot help thinking that they are best regarded as varieties of the same thing.

The causes of epilepsy are diversified and numerous. Occasionally it is found to be a hereditary ailment, but it is oftener consequent upon some functional or structural change in the system. In early life the most common causes are irritation—from teething, from worms, from mesenteric disease, from debility, or from some unknown alimentary disorder; hydrocephalus, also, and the sources of it, are frequent originators of the convulsions of children; not rarely it has been observed in connection with undue cerebral development. In the adult, also, the causes of epilepsy are various. Gastro-intestinal disorder is not an unfrequent source of the ailment; whatever prostrates the powers of the nervous system has the same tendency; it has been found associated with, and seemingly the result of, disease of the liver, heart, kidneys, and uterus, but most commonly of some altered condition of the brain or its investments—such as inflammation, congestion, extravasation, effusion, tumours, exostoses, softening, tubercles, abscess, and injury from external violence; often it attends upon amenorrhæa, or the period of menstruation; and often, again, it has no evident pathological connections, and necropsy throws no light upon it.

In treating epilepsy it is paramently necessary that you first search for the cause of it: that is what you have to contend with. Always bear in mind that the convulsions do not constitute the disease: they are only symptoms of a more remote and more serious suffering. If this appear remediable, attack it at once with the best remedies you have; if it arise from organic and incurable causes, you must be satisfied to palliate. The various sources of epileptic seizure will suggest to you that there can properly be no routine treatment instituted, but that every case must be judged by its pathological manifestations, and prescribed for accordingly.

The first case of epilepsy treated in the hospital, to which I wish to direct your attention, was in the person of Henry Bayliss, who was admitted under my care on the 24th of March last. He had suffered from epilepsy for more than two years, and had been under the care of several practitioners, but without any benefit. He was twenty-one years of age, very stoutly built, with a tendency to plethora. Had not led a dissipated life, and could not account for the occurrence of his fits. Lately he had little employment, and scarcely a sufficiency of food, and his epileptic attacks (seemingly in consequence) had increased in force and frequency. Sometimes he would not have a fit for two or three days, and then would have half a dozen in as many hours. Usually he had a fit every morning, either just before or just after rising. The convulsions were not severe, and generally lasted for ten or fifteen minutes. The patient had a stupid look, but did not complain of drowsiness, or any pain in his head, or singing

A COURSE OF LECTURES ON CLINICAL MEDICINE.

Delivered in the Theatre of Queen's College, Birmingham.

By SAMUEL WRIGHT, M.D.

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and formerly Senior President, of the Royal Medical, Royal Physical, Hunterian Medical, and Cuvierian Natural History Societies of Edinburgh, &c.

Epilepsy; difficult to treat, especially in the adult subject; infantile epilepsy, and that of childhood, more tractable; observations thereupon; distinguishing symptoms of epilepsy; their variation in different individuals; causes of epilepsy in early and adult life; treatment of it; convulsions to be regarded secondary to their cause; treatment in-

in his ears; his eyes were bright, and pupils natural; his appetite was capricious; tongue furred in the centre; bowels costive; pulse small, hard, and of proper frequency. He had almost constant pain in the epigastrium, increased on pressure, and he suffered much from gastro-intestinal flatulence.

The general aspect of this case inclined me to look upon the epilepsy as arising from a disordered state of the stomach and bowels, and the more so because the man had often been bled and blistered, but without deriving the least benefit from such treatment. He was ordered the following:—

R. Infusi quassiae, ℥viij.; solutionis strychniae, ℥ij.; tinct. zingiberis, ℥ij. M. ft. mist. cujus cap. coch. ampla duo ter die.

Each dose of the mixture contained one-sixteenth of a grain of strychnine.

R. Scammonii, jalapae, aa. ℥ij.; hydrarg. chlor., gr. iv. Misce et divide in pulv. vj. equibus cap. j. omni mane.

During the first week of this treatment, the man had not a single fit, and his general health so much improved that I was almost inclined to think he would soon be well. The week, however, had scarcely elapsed, when the convulsions returned, and were more severe and rapidly successive than they had been for months past. It seemed as if the increased strength of the patient were all thrown into his paroxysms. From this time the strychnine disagreed with him, and, as he expressed a dislike to it, I substituted the following tonic, the gastric condition still inclining me to the opinion that therein was the chief disorder:—

R. Inf. quassiae, ℥viij.; tinct. ferri sesquichloridi, ℥ij. M. fiat mist. cujus cap. coch. larga duo ter die. Cap. omni nocte, hora somni, pil. coloc. a. gr. x.

Under this plan the man again improved; he had only two fits during the first week of taking the iron, and not a single fit during the three subsequent weeks. He became more lively and active, lost his flatulence, and had scarcely any epigastric pain; his appetite was good, and digestion easy.

Again, however, he relapsed, and his convulsions became as violent and frequent as they had ever been. We pushed the iron some days longer, but to no purpose; it began to disagree with the patient, and he complained that it made him sick and chilled his stomach. The fur was again upon his tongue, and the flatulence had returned.

R. Infusi cusparae, ℥viij.; ammon. carb., ℥ij. M. ft. mist. cap. coch. magna duo ter die. Contr. pil. ut antea.

This form of tonic benefited him for a few days, during which he was free from convulsions. But they returned again, and it was clear we had made no real advances towards recovery. Pain at the back of the head now came on, not severely, but still I thought it best to be suspicious of it. Depletive measures were rather contraindicated than otherwise, and I therefore provided a steady drain and counter-irritation, by a seton at the back of the neck. This was the object of preventing congestion or inflammatory action in the brain, at a small sacrifice of general strength. The head was relieved in consequence, and the fits abated for a few days, but only to return again, neither lessened in force nor frequency. We then suspended the mixture, and tried the oxide of silver in the following form:—

R. Pil. coloc. c., ℥ij.; pulv. rhei, ℥j.; argenti oxydi, gr. iij. Misce in massam, dividendam in pil. xij. quarum capiat j. ter die.

For several days I thought some benefit was being derived from this plan; the stomach and bowels had recovered a proper tone and function, and the fits decreased both in number and severity. Before a fortnight had elapsed, we were again disappointed in the unmitigated return of the convulsions. There was, however, no pain in the head, or the least evidence of cerebral congestion; the tongue was less furred than before, there was little flatulence, the bowels were

well open, and the appetite good. We continued the pills night and morning, and additionally tried the sulphate of zinc in mixture, as follows:—

R. Zinci sulphatis, ℥j.; acidisulph. dil., ℥j.; mist. camphorae, ℥viij. M. ft. mist. cujus cap. coch. larg. duo ter die.

When three days had elapsed we increased the quantity of sulphate of zinc to half a drachm, and then to two scruples. Some amendment took place, decidedly, but, like all aforetime, it was only temporary.

On the 6th of July the seton was obliged to be removed, on account of an erysipelatous inflammation that had seized the part, and was threatening to extend itself. It did extend, and implicated the whole face and neck in one of the most serious forms of erysipelas I ever saw. The treatment now used I will detail to you in my next lecture, which will embrace the subject of erysipelas chiefly; I must, therefore, speak of my patient again after his recovery from the cutaneous inflammation. He was convalescent from this on the 16th, at which time he was taking bark and ammonia; his gums were slightly tender from the mercury that had been given, and though we had not bled him he was considerably reduced. During the prevalence of the erysipelas he had no fits, nor for above a week after his convalescence. I was not without a hope that his more acute ailment might supersede the chronic one, but again I was disappointed.

On the 25th the fits returned, but mildly, and not oftener than twice or thrice daily. At this time the patient was very feeble; he had no pain in his head, or confusion of vision, or any single symptom of cerebral disturbance; he complained of sinking at the epigastrium, and great lassitude. The ammonia and bark were continued, with an occasional aperient. Beef-tea, mutton-chop, and other nutritives, were ordered at stated intervals. He remained in much the same state until the 2nd of August, when strong reaction commenced; the skin became hot and dry; pulse 100, and firmer than usual; urine scanty and high-coloured; fits frequent. Still there were no cerebral symptoms. Feeling suspicious of this sudden reaction, but at the same time not daring to deplete, I ordered the following:—

R. Sodae bicarb., vini ipecac., tinct. digitalis, aa. ℥j.; aquae, ℥viij. Misce; cap. coch. ampla duo tertia quaque hora. The feet to be immersed in hot mustard and water at bedtime. Low diet.

On the following morning the fever was still higher; head hot, with oppressive pain all over it; pulse 110, small and hard; bowels moderately open. Ten leeches were immediately applied to the temples, and their bleeding maintained for three hours; five grains of calomel were given at once, and a turpentine enema half an hour afterwards. The mixture to be continued. These means were of no avail. The convulsions became more frequent, though they diminished in individual severity, until a few hours before his death, when he became calm and semi-comatose, and died early on the morning of Aug. 4.

The *post-mortem* discovered some congestion of the superficial vessels of the brain; none of its membranes or substance. There was slight subarachnoid effusion, but this was quite clear and free from lymph. About half an ounce of perfectly clear fluid was found in each lateral ventricle, and about the same quantity at the base of the brain. A triangular piece of bone, three-quarters of an inch long, and half an inch broad at its base, was found in the folds of the *fals cerebri*, lying upon the summit of the left hemisphere of the brain; it did not press into the latter, or appear in any way mechanically to interfere with it. The only other strange appearance in the body was concentric hypertrophy of the left ventricle of the heart: the cavity was not large enough to contain more than three quarters of an ounce of fluid, and its walls were, in places, an inch and a half in thickness.

In this case the gastro-intestinal disturbance

stanced in its persistence, and in the temporary relief frequently afforded by tonics. Yet these did not effect a cure, which may, perhaps, leave us in doubt whether the radical affection were alimentary. Then there was the bone in the *fals cerebri*; less deposits than that within the cranium have committed injury and proved fatal, and yet it is somewhat singular that, if this were the source of the convulsions, these should vary according to the state of the stomach and bowels. The vascular condition of the brain's surface and the nature of the effused fluid clearly showed that these were only of recent date—the former not more than forty-eight hours, the latter much less, from the period of death. It is clear, therefore, that this cerebral condition had no share in the earlier epilepsy. Perhaps some irritation caused by the osseous deposit in the *fals*, increased sympathetically by any disturbed condition of stomach and bowels, was the source of the epilepsy as it originally existed, and continued until the last severe seizures; the latter were plainly due to congestion, which, though not active and coming upon a state of prostration, was yet enough, under predisposing circumstances, to quickly terminate the patient's existence.

Some weeks back we had a patient named Marshall, in the top ward, the subject of that form of epilepsy which I spoke of as being sometimes mistaken for a fainting fit. He was very pale and rather emaciated-looking. His fits used to occur in a morning, and, with scarcely perceptible convulsion, left him prostrate and powerless for hours. I could not learn the history of his ailment, but I suspect the cause of it to have been due to some youthful improprieties. His tongue was always clean, and appetite and digestion good, but he had a feeble and sometimes intermittent pulse, and the systolic sound of his heart was indistinctly audible. He improved under the use of a bitter infusion with ammonia, and good living; but we were compelled at last to dismiss him on account of his propensity to lie in bed, and to give exaggerated reports of his ailment.

In the same ward I have at present an epileptic patient, a little boy, ten years of age. His ailment is of about eighteen months' duration. He has no pain in his head or any other indication of cerebral disease; but his tongue is always furred, and he has epigastric tenderness. His pulse is good, appetite variable, bowels generally costive. At first I suspected he had worms, and gave him various anthelmintic purges, but without producing any good effects. I then tried him with a light chalybeate tonic, that proved serviceable for a time, and then its efficacy failed; next I gave him a bitter infusion with ammonia, but whilst taking this, his fits strangely increased in number and force; oxide of silver was next given, but after a fair trial I was not satisfied that it had been of any use; at present he is taking sulphate of zinc in solution, in doses of five grains each (three grains was the commencing dose), and it has done him more good than anything. He has taken it for more than a month, and the fits have systematically diminished both in force and frequency. This boy bids fair to get well; but my acquaintance with the uncertainty of the disease does not leave me at liberty to indulge in more than a qualified hope.

There is an out-patient named Wilkins, an epileptic, who has been under my care about five weeks. The only pain this man complains of is across his eyes, and at the pit of his stomach. I expect that disturbance of the latter organ is the pathological fault. The frontal headache is increased after meals, and the epigastric pain is worst when the stomach is empty. The tongue is deeply furred; bowels costive, and generally flatulent. Aperients were first tried, with vegetable tonics and soda, but without effect. Then we gave chalybeates, but they were also unavailing. Next we tried ammonia in a bitter infusion; that did good, but it was only for a time. Then we gave oxide of silver, as I have previously prescribed it, but its services, again,

were only temporary. He is now taking sulphate of zinc, in doses of four grains three times a day, and during its use has been certainly better than ever whilst under my care. At the same time, I am not unprepared to find him, some morning, as bad as he has ever been.

A week ago I admitted an out-patient, named Harriss, the subject of epilepsy. Her fits, which occur most days, and often more than once daily, came on about two months ago. She is seventeen years of age, and rather more than four months since ceased to menstruate. She had previously been very regular, had enjoyed excellent health, and had no apprehension or forewarning of her fits. In this girl's case there is nothing to indicate that other than uterine causes are operative in the production of her convulsions. She is taking warm purgatives, with chalybeate tonics, living well, and walking three or four miles daily. I think the restoration of her uterine function will be marked by a cessation of her convulsive fits.

You have seen one or two cases of epilepsy in children cured by purgatives that have caused the discharge of worms. These cases, however, require no comment.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILLSHIRE, M.D. (Edin.), M.R.S.,
Physician to the Royal Infirmary for Children, &c.

(Continued from page 426.)

I occupied your time at the last lecture, gentlemen, in reviewing some points of differential diagnosis in relation to tuberculous meningitis and other disorders. Before proceeding to consider the treatment of the former, I must say a few words on the "pathogeny" of the affection, the more so as the arriving at a true interpretation of it is the sole guide we have for our therapeutic interference. I shall say nothing about the opinions held upon the point in question before the times of Quin and Rush, because they were the earliest, I believe, who, proceeding upon the evidences of morbid anatomy, endeavoured to arrive at a right conception of the truth. From their investigations, and those of others, up to the present time, a very numerous class believes that, to use the words of an eminent practitioner, "the disease is clearly inflammatory, and the treatment of inflammation is that which is demanded for its cure;" in fact, another writer has remarked that this doctrine "has become a household creed." In late times, however, very different views have been held of *acute hydrocephalus*, both as regards its pathology and therapeutics, more especially by the continental writers.

The main point for you first of all to become satisfied of is this, that, although there may be inflammation of some kind, degree, or peculiarity involved in the series of diseased actions at some one or other of the stages of their development, the inflammation never occurs as the consequence of temporary external influences alone; or, although its outbreak may be excited by some disorder already existing, the more general and fundamental origin of it lies in a different direction. Next, that there occur cases of *acute hydrocephalus* characterized by lesions not necessarily involving inflammatory action in their production or sequence—such as softening, ventricular effusion, and granular deposit. Lastly, that that form of disorder—*acute* in its march and character, rapidly advancing to a fatal result if permitted to run on, but often subdued by the interference of remedial measures—although called *hydrocephalus* by many, is a different disorder altogether, and does not constitute the common *hydrocephalus* which we usually observe. The former is the "disease clearly inflammatory in its nature, and the treatment of inflammation is that which is demanded for its cure;" it is that which is an independent inflammatory process, either completely idiopathic or occurring as an intercurrent affection of

some febrile disorder; it is that which may be found independent of any primary constitutional vice; it is that which may be produced alone by external influences. It is true simple meningitis—it has nothing specific about it like the other. What is this other? It is an open manifestation of the scrofulous diathesis; it is tuberculosis with its attendant phenomena attacking the membranes of the brain; it is scrofulous disease of the nervous centre. This manifestation of scrofula varies in different cases, but the common form is that of the exudation of tubercular granulations, accompanied with meningitis—it is tuberculous meningitis: it is this which is the common water on the brain, which disorder, in many cases, has, as a characteristic, effusion of fluid in the ventricles.

But what more particularly, may it be asked, are the characters of the *local action*, although it be admitted the scrofulous or tuberculous state of body is the foundation of it all? We find the lesions to be exudations, effusions, softening, and congestion. Which of these necessarily indicate there has been increased vascular action or inflammation in the brain or its membranes? But few of their forms necessarily indicate the previous or present existence, or would involve the future of such a state at all. Have we, then, no evidence of inflammation being included in the series of diseased actions constituting "acute hydrocephalus"? In the majority of cases we have—we have such evidence afforded both by symptoms and *post-mortem* phenomena. In the combination of cephalalgia, increased sensibility of eye and ear, fretfulness if disturbed, heat of scalp, tense pulsating fontanelles, vomiting, &c., all signs of irritation, with vascular congestion, effusions of concrete lymph or purulent matter, or milky effusions at the base or on the hemispheres of the brain, and along the course of the meningeal vessels as seen after death, we find enough evidence to warrant us in saying that inflammation has existed.

But do we *always* have such combination of symptoms and morbid appearances? We do not. We may have all the symptoms, and yet no such morbid phenomena. We may have, in lieu of the latter, either granular deposit and effusion in the ventricles, or the former with softening and no effusion; we may even have great effusion with scarcely any softening, or but very slight granular deposit.

You know, too, that, except in a few cases, exudation of the granular matter always accompanies what evidences of the inflammation may exist.

Now, I need not, after all I have said on scrofula, attempt to prove that this granular deposition or exudation of the tuberculous matter usually ensues without having inflammation as its cause or forerunner. It would be beyond the intention of these lectures to show you that that peculiar lesion called *white softening* is not the result of inflammatory action; and you must accept from me, as the truth, that an effusion of serum may ensue without being produced by an inflammatory action, and that this is especially the case in the scrofulous or tuberculous diathesis. I refer you to the writings of Schwenninger, Bright, and Bennett.

Although admitting, then, that in a great many cases there has been inflammation, as shown by the morbid phenomena; and also—or, if you like it better—very great irritation, as shown by the earlier symptoms during life, yet it may be affirmed this inflammation is not of the common kind. We find, too, that in others the disease runs its course without any traces, after death, necessarily inferring the previous existence of this action, and with much the same symptoms as it does where such traces exist. Not only this, but we have every reason to believe that, even in those cases in which there is distinct proof of inflammatory action having preceded the fatal event, this action is, in most cases, a secondary phenomenon, and is caused by other more primary and important changes in the brain or its coverings.

We are led, then, to infer other causes besides

mere inflammation as the pathologic essence of this disorder; we are forced to look for a more primary derangement, of which congestion, inflammation, softening, and effusion, are effects, not causes. From the fact of this disorder being so constantly connected with the scrofulous diathesis, from the more constant morbid lesion met with after death being tubercular or granular deposit, from the frequent co-existence of tuberculosis of other organs during its course, we are led to infer its connection with scrofulous or tuberculous disorder. This connection is still further strengthened by the fact that the assumption of its being a *common inflammation* helps in no way to explain the nature of the disease—nay, such assumption is *negated* by the latter giving us proof that it often kills without leaving any traces behind it which necessarily prove the existence of that morbid action. Not only this, but, when we are sure this action has ensued, it does not sufficiently explain the symptoms during life as being entirely dependent on it and its sequences: for from what we know of those cases, which may truly be regarded cases of simple meningitis, the symptoms, course, and progress of the malady, as also its *post-mortem* phenomena, are different to those of our present disorder, and which inflammation also seeks to explain. It is also allowable to fortify our argument against the view in question by our producing proof that the therapeutic indications followed out on the above assumption have no power of arresting the malady; but, on the contrary, will often hasten the fatal event.

From the peculiarity of symptoms and course of the malady, from the morbid appearances after death, and from the result of particular modes of treatment, as well as from the constitution of body in which it occurs, and its correlation to other disorders, we deny, then, that "acute hydrocephalus" is a common inflammatory disorder. Suppose it be admitted, then, on the other hand, that it is a manifestation of scrofulous disease, it may be asked, how are the local phenomena to be explained? The most frequent of them, you know, is the granular deposit, or tuberculous matter. This, I have already told you, is, in the greater number of cases, deposited as a subversion of the healthy act of nutrition; and that, if the state of the blood be very bad, and the constitutional tendency to persist in forming it so be very great, organic assimilation of any of the more important organs can scarcely be attempted in children without being accompanied by this non-vascular, aplastic, albuminous deposit. (a)

The next more frequent phenomenon is ventricular effusion. In the scrofulous or tuberculous diathesis the blood is unusually serous; and you know that, of all the conditions of this fluid inclining to effusion, a poor or watery one is the most general, both from the greater tendency watery blood has to transude through the parietics of the vessels, and also by the failure and irregular distribution of the force of the circulation occasioned by such a fluid; and we know that the movement of it within small vessels in the scrofulous diathesis is very sluggish. "What is the precise essence," says Dr. Bright, "of the scrofulous diathesis, or how far it depends upon the construction of vessels, or in how far it is to be ascribed to the direct influence of the nerves, still remains a matter for investigation; but that the feeble powers of resisting mischief which accompany this diathesis greatly predispose to disorganization, and more particularly to effusion, is most certain; and even when no tubercular disease can be detected the effusion of serum in the form of hydrocephalus frequently occurs."

In relation to this point, Schwenninger writes so appositely, that I cannot refrain quoting from Dr. Bennett's translation of the paragraph. He says,—"A slight glance at the symptoms and *post-mortem* appearances of tubercular diseases in general will show us that nothing is

(a) *Vide Medical Times*, No. 397, page 210; also Carpenter.

more common than preternatural effusions of serum either as the product of secretion or excretion. Edema of the feet, and general anasarca, frequently occur, not merely in the latter stages, but repeatedly in the course of such diseases. A more abundant secretion of fluid from the arachnoid and into the ventricles of the brain is found in phthisical subjects than in those dying of most other diseases. Hydropericardium is also common, as well as oedema of many of the other internal organs. . . . If serous effusion be a common occurrence in tubercular disease in general, we need not be surprised that in children it should so frequently occur in the brain—an organ which in childhood is in a state of high organic functional development."

The next lesion I have to notice is the *white softening* which is met with. In hydrocephalus we meet with "ramollissement" of the central part of the brain, which in certain cases undoubtedly must be referred to the absorption of ventricular effusion, giving rise at first to oedema of the ventricular parietes, and afterwards to pulpy disorganization. This kind of softening may be produced either by infiltration of the fluid during life, after the distention of the ventricles has produced rupture of some portion of their walls, or after death by the simple imbibition of the fluid in question by the structures surrounding it. This you will find is proved by the researches of Billiet, Guillot, and Paterson, although Rokitsansky denies it. But there is another kind of softening, which is certainly no more referrible to such causes any more than it is in those cases to inflammatory action; and it is this softening which is an important element in the pathology of the disease. Not that inflammatory action cannot or may not produce it, for sometimes it does; but the softening of tuberculous meningitis does not own it for its cause, for we have it existing, and yet no evidence of such an action having ensued, unless the softening itself be assumed to be such; and this, you know, would be what logicians call a *petitio principii* at once, and therefore we cannot argue the matter. What does it depend on? On a specific alteration in the act of nutrition, of organic assimilation, closely connected with that condition of blood and small vessels we see in the dyscrasia of scrofula.

Lastly, it must be admitted, as before remarked, that the effusion of lymph, of concrete pus, together with the frequent congestion of the vessels along the course of which, in the membranes, these effusions are more frequently seen, are evidences of inflammation having existed when such effusions are observed. But, admitting that, it is still to be asked, Is not this inflammation, in the majority of cases secondary or consequent upon, or intercurrent with, the granular deposit? Does it not owe something as a cause—which is the true essence of the disease—instead of it being the disease itself? Not only this, but is not that form of inflammation which we see connected with the deposition of tuberculous matter, or which we call scrofulous inflammation, of so specific a character that, even admitting a disease was characterized by its supervention, we should have to reason upon it, so far as practical purposes were considered, in a different way to which we should in reviewing a disorder marked by inflammation of the simple common, or, as it is often called, *healthy* form? But in this disorder we have also fatal cases occurring, in which we have scarcely any satisfactory evidences that inflammation even of this secondary specific character has occurred at all. How, then, can inflammation constitute the disease we have regarded as the commonly observed form of "water on the brain"? Broadly as this doctrine may be asserted, it is, however, equally as true that tuberculosis of the meninges, &c., may be preceded by congestive or scrofulous inflammation in particular cases; and, therefore, when cerebral congestion appears in a scrofulous child, we must be careful in the extreme as to the consequences which may follow. It is equally cer-

tain, to my mind, that in the great majority of cases the deposit of tuberculous granules, &c., is the primary local mischief which produces the local irritation, giving rise to the inflammation, and which increased vascular disturbance, must be regarded as different from the common type.

Pulmonary tuberculosis is not an inflammatory disorder; but congestive or scrofulous inflammation may in some cases precede the morbid deposit. Tuberculosis of the lungs mostly precedes the local congestions, which, when they exist, are primarily caused by the irritation of the deposit. Although such congestions or inflammation, in phthisis, may give rise to serious results, yet phthisis is not an inflammatory disorder. So must we reason in a like manner with regard to *tuberculous meningitis* or "acute hydrocephalus."

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART X.

ELECTRIC FISHES.—CURRENT PROPER OF THE FROG.

Of the five species of electric fishes known to us at present, viz., *raia torpedo*, *gymnotus electricus*, *silurus electricus*, *tetodon electricus*, and *trichinus electricus*, the two former alone (and more particularly the *raia torpedo*) have been the subject of careful and attentive study.

The seizing of a live torpedo with the hands is speedily attended with strong electric shocks in the wrists and arms, similar to those produced by a pile constructed of from 100 to 150 elements, and charged with salt water; these shocks succeed one another sometimes with such frequency and rapidity as to become quite unbearable. After the lapse of some time, however, the animal loses its vivacity, and the shocks become less vigorous. The electric shock given by the torpedo is sufficiently strong to be felt, even though the recipient be not in immediate contact with the animal; thus, whenever there happens to be a torpedo among the fishes in the nets of a fisherman, the latter is speedily made aware of its presence by feeling electric shocks, more particularly in the arms, upon throwing water in a continuous stream upon the fishes (for the purpose of washing them). The torpedo has the power to communicate this shock even at considerable distances through the water in which it exists—a faculty which seems to have been bestowed upon this animal by nature in order to enable it to kill the fishes intended for its food.

The identity of the phenomena presented by the torpedo with those of the electric force has been long established. Numerous experiments have fully demonstrated that the phenomena of the electric discharge and shock of the torpedo are to be attributed to an electric current generated in two particular organs, denominated *electric organs*, and of which the dorsal face is positive, the abdominal negative. The electric discharge is a voluntary act on the part of the animal, and all external excitation acts upon the electric organ solely by the intermediacy of the will; indeed, as the discharge would pass actually through the body of the torpedo were there not external circuits and conductors to receive it, it is obvious that the animal would immediately cease to give electric discharges if removed from the water, or touched with irritating bodies or left altogether untouched. It is not without reason, therefore, that nature has placed animals endowed with this faculty in a conducting fluid.

If one of the electric organs of a living and vigorous torpedo be rapidly severed from the covering and surrounding cartilages and integuments, leaving intact the large trunks of the nerves, alone which spread their ramifications through the organ, the latter will continue to exhibit the usual electric phenomena—which proves that the cartilages, integuments, &c., are without the slightest influence upon the discharge of the electric shocks; and shows likewise that the circulation of the blood is not absolutely indispensable for the manifestation of the electric phe-

nomena. If the organ thus severed from the animal be covered with frogs prepared in the usual way, and the conductors of the galvanometer be applied respectively to the two faces, excitation of the nerves will be immediately followed by contractions of the frogs, and deviation of the needle indicating the circulation of an electric current from the dorsal to the abdominal face of the organ.

When proceeding in this manner, another very curious phenomenon is observed, viz., the discharge is obtained at one time in one, at another in another, portion of the electric organ; to perceive this clearly, it suffices to excite separately and singly each one of the nerves of the organ, when those frogs alone will be seen to contract that are placed upon one of the ramifications of the excited nerve.

These discharges are obtained only for a very short space of time, which may be lengthened, however, by passing an electric current through the nerve of the organ thus severed from the animal: this current obeys here the same laws which regulate its action on the muscles. It excites the electric discharge at the moment it commences to circulate in the nerve of the organ; this discharge is not repeated whilst the current continues to traverse the nerve, but may be excited anew by interrupting the current.

The parenchyma of the electric organ continues to retain the electric property for some time, although completely severed from the animal and pierced and cut in various directions; but it ceases to manifest electric phenomena if the albumen which enters largely into its composition is coagulated, either by immersing the organ in boiling water, or by subjecting it to the action of acids.

The preceding facts prove that the electric discharge of the torpedo is under the direct influence of the will of the animal, which is transmitted through the nerves spreading their ramifications in the electric organs. These nerves are thus neither sensory nor motory, and have no other function except to excite the action of the organ in which they are distributed.

With respect to the influence which the brain exercises upon the discharge of the torpedo, the author has ascertained, by a series of experiments, that the olfactory and optical lobes of the brain and the cerebellum are altogether unconnected with the electric phenomena presented by the animal, and that the fourth lobe (denominated by the author *electric lobe*) alone is most intimately connected with these phenomena: the three former parts may be removed without impairing the electric faculty of the animal, whereas the removal or radical lesion of the fourth destroys this faculty for ever, even though the other three lobes be left intact.

The torpedo ceases to manifest its electric properties when immersed in water of 32° Fahrenheit, but it recovers them upon immersion in water of from 59° to 68° Fahrenheit. In water of about 86° Fahrenheit, the torpedo dies speedily, the extinction of life being attended with a great many violent discharges.

The discharge of a great many successive shocks seems to exhaust or suspend the electric faculty; rest restores it.

Narcotic poisons (strychnine, morphine, &c.), given in large doses, kill the torpedo speedily, the extinction of life being attended with a great number of vigorous and rapid discharges; small doses of these poisons put the animal into a state of extreme excitement, when the slightest irritation suffices to provoke electric shocks. The section of the spinal marrow deprives the parts situated below the cut of the power of giving electric shocks; which proves that the electric discharge is produced by reflex action upon the spinal marrow.

The analogies between muscular contractions and the discharge of the torpedo are complete: everything that destroys, augments, or modifies the one, acts equally and in the same manner upon the other.

The *gymnotus electricus* has not been so fully studied as the torpedo. From Faraday's and the

author's observations and experiments it results, however, that the electrical phenomena presented by this animal are also identical with those of the electric force. Faraday has established that the cephalic extremity of the gymnotus constitutes the positive, the caudal extremity the negative, pole. Faraday calculates the discharge of the gymnotus equal to that of a charged battery of fifteen bottles, representing a surface of 3500 square inches English. The author observed that the gymnotus possesses the faculty to discharge either part only, or the whole, of its electric organ. This requires, however, further confirmation.

According to the important anatomical researches and observations of Savi and Robin, the electric organ of the torpedo is composed of a certain number (about 100 to 500) of prismatic vesicular masses, resembling grains of rice—the whole organ presenting the aspect of a honeycomb. Each of the component prisms presents a certain number of partitions, dividing it perpendicularly at its axis, and which seem to consist simply of the aponeurotic walls of the adjoining vesicular masses. Nervous ramifications are distributed over these partitions. These ramifications result from elementary fibres disseminated in meshes over the walls of the vesicles, and terminating in links in the electrical lobe, and most probably likewise on the walls of the vesicles. The nervous ramifications of the electric organ would accordingly form a great number of closed circuits, having each of them one link in the electric lobe, and the other in the wall of the vesicle of the electric organ. The close resemblance or, more properly speaking, the identity of structure presented by the vesicles of the electric organ leads us to look upon these vesicles as the elementary organ of the electric apparatus; this hypothesis is supported, also, by the identity of composition which they present—every one of them being filled with a dense fluid, composed of nine parts of water, one part of albumen, and a little sea-salt. The author has demonstrated by direct experiments, that each of these vesicles forms one of the units which constitute the sum of the elementary organs of the electric apparatus. He removed from a living torpedo a piece of one of the prisms of the electric organ, and placed the removed piece (which was about the size of a large pin's head) in contact with the nerve of the galvanoscopic frog; he found that the frog contracted when the fragment was pricked with a piece of broken glass or some other pointed substance.

Now, if we reflect that each of these prisms (of which Hunter counted 470 in one single electric organ of the torpedo) is composed of a very great number of vesicles or elementary organs, we can readily account for the intensity and vigour of the discharge, considering that this must be proportional to the number of vesicles.

The electric organ may, accordingly, be looked upon as a real multiplier apparatus.

Volta's hypothesis, viz., that the electric organ should be considered a pile, which the animal puts into action by compressing the organ, and thus establishing a contact between the latter and the skin, has not been confirmed by the results of the experiments made on the torpedo. It has recently been asserted that the electric organ of the torpedo is analogous to an electro-magnetic spiral, and also that the discharge from it is a phenomenon of induction. When we reflect that microscopic observation has demonstrated the existence of a nervous filament in every one of the vesicles composing the electric organ, we find it difficult to discover this pretended analogy between the electric apparatus of the torpedo, and an electro-dynamic spiral.

Another hypothesis may be started which, as we shall see hereafter, is supported by some facts, or, at all events, by very strong analogies. Let us suppose that the two opposite electricities separate each time that the nervous excitation arrives at one of the elementary vesicles of the electric organ of the torpedo. As heat, chemical and mechanical action, friction, pressure, &c.,

effect this separation of the two opposite electricities in other bodies, we have some reason to suppose that the nervous excitation may act in a similar manner upon the vesicle of the electric organ; the identity of structure and disposition of the vesicles warrants us to assume that every one of the prisms composing the electric organ forms a pile, but only for the infinitely short period that the excitation lasts: the electric organ may accordingly be considered as a multiplier apparatus which remains charged only for one instant—placed, as it is, in the midst of conductors. The discharge will take place, according to this hypothesis, partly in the interior of the organ, and partly on the outside in the surrounding medium; but the outside discharge will be the stronger, in proportion as the surrounding medium happens to be a better conductor than the interior of the organ. (That this discharge really takes place in the interior of the organ has been proved experimentally.)

From this hypothesis it would result that the opposite electricities should invariably be found at the longitudinal extremities of the prisms, and their intensity should be proportional to the length of these prisms, or, in other words, to the number of cells composing each of them. Actual observation and examination of the organs of the torpedo and gymnotus tends to confirm these hypotheses.

The relative position of the poles in the gymnotus corresponds to that of the poles in the torpedo, as regards the extremities of the prisms. In the gymnotus the prisms extend along the axis of the body of the animal, or, in other words, from the tail to the head, or *vice versa*. In the torpedo, on the other hand, the extremities of the prisms are respectively in contact with the back and belly. The head and tail are accordingly the poles in the gymnotus, whilst in the torpedo these poles are found on the back and belly.

The structure of the electric organ in the silurus would likewise lead us to place the poles in that fish at the head and tail, as in the gymnotus.

The electric discharges are the most intense in those points of the organ which are nearest the median line, where, likewise, the height of the prisms and the number of nervous filaments are the most considerable.

For a more intimate and satisfactory knowledge of the electric organ of these fishes we must look to the future investigations and revelations of microscopic anatomy.

The phenomenon which takes place in the electric organ is certainly analogous to electric induction: the constancy in the direction of the discharge supposes a definite direction in the action of the nervous force; and this supposition seems not without foundation, when we consider that the excitation of the fourth lobe and of the electric nerves has no other effect except to produce the discharge.

We come now, finally, to another phenomenon of animal electricity, viz., the *current proper of the frog*.

Galvani discovered that a frog, prepared in his usual way, contracts when the lumbar nerves are brought into contact with the muscles of the thigh or leg. Nobili was the first to study this phenomenon with the galvanometer. His fundamental experiment may be readily repeated:—Take a frog, prepared in the usual way; place it into two small glasses, filled with distilled water in such a manner that the lumbar nerves are immersed in the water on the one, and the legs on the other, side. Close the circle by immersing into the two glasses the two platinum wire extremities of the galvanometer: you will observe that the needle deviates to the extent of 10° , or even 15° ; and that the direction of the deviation indicates a current circulating from the legs to the nerves, or, in other terms, from the legs to the upper part of the body of the animal.

These indications of an electric current will increase in intensity if, instead of using a single frog, the experiment be made with a pile of frogs. The author found in his experiments upon this

subject that the degree of deviation of the needle is proportional to the number of frogs composing the pile; that the deviation is more marked when an alkaline, or saline, or, better still, acid solution is used instead of distilled water; and that the direction of the current is constant (from the legs to the upper part of the body of the animal), whatever the nature of the liquid used.

At the same moment that the galvanometer indicates the presence and direction of the current the frogs exhibit contractions.

These contractions are analogous to those observed by Galvani; they take place each time that the circle is completed with a conducting body, such as a cotton wick or piece of paper imbibed with water, or any conducting liquid whatever, provided, of course, that the conducting body be disposed in a manner to touch the nerves of the animal on the one, and the muscles on the other, side; these contractions are again observed at the moment that the circuit is broken.

This current has been denominated *current of the frog*; the author has substituted for this "*current proper of the frog*," because, till very lately, its existence seemed confined to the frog alone. The current proper of the frog exists exclusively in the leg of the animal.

The author has recently discovered that this current, which was hitherto deemed peculiar to the frog, is a phenomenon appertaining to all animals. The simple statement and explanation of the fact is this: all muscles endowed with life, and in which the tendinous extremities are not equally distributed, present the existence of an electric current in the interior of the muscle, directed from the tendon to the muscle. All animals have some muscles in which one of the tendinous extremities is less broad than the other—the one presenting the appearance of a sort of string, the other that of a ribbon. This is the case with the gastrocnemius of the frog, and of some other animals, and with the pectoral muscle of birds. A pile constructed of these muscles presents an electric current circulating in the muscles from the tendinous extremity to the muscular surface. Care must be taken, in the construction of such piles, to avoid laying bare the internal part of the muscle, and the elements must be placed in contact with one another in such a manner that the tendinous extremity touches invariably the surface of the muscle, and is as far as possible removed from the interior. If this precaution be neglected, the circle will include the *muscular current*, which, being directed from the interior to the surface, would follow a direction the very reverse of that of the *current proper*.

Having thus established the conditions upon which the current proper depends, the author proceeds to assert that the muscular current and current proper have one and the same origin in common. The correctness of this assertion he maintains principally upon the ground that the divers causes which modify the organism and life of animals act in the same manner upon the muscular current and upon the current proper.

Anatomists have recently demonstrated that the elementary muscular fibrils merge immediately and without interruption into the tendinous fibrils, and that the sarcolemma which invests the muscle terminates abruptly at the point of insertion or union between the muscular and tendinous fibrils. The tendon may accordingly, with some reason, be considered to possess the same electric condition as the interior of the muscle, and we may, therefore, assume that a portion of the muscular current is put into circulation by establishing, by means of a good conductor, a galvanic circle between the tendon and the sarcolemma investing the muscle.

PART XI.

PHYSIOLOGICAL ACTION OF GRAVITY, LIGHT, AND HEAT.

Under the heading of "*Physiological Action of Gravity*" we mean here simply to treat of a peculiar phenomenon observed in the development

of plants, and in which it would be impossible not to recognise the influence of gravity.

Generally speaking, all plants exhibit in their germination and growth the tendency of the roots to descend and of the stalks to ascend. Experience has demonstrated that this opposite tendency of the different parts of the plant is attributable neither to the humidity of the soil, nor to the action of light or of the atmosphere. The roots will continue to descend, and the stalk to ascend, even if the order of Nature be inverted and the stalk placed in contact with the soil and the roots exposed to the light. We are indebted to Knight for some ingenious experiments which, though they have not fully enlightened us upon the subject, have at all events demonstrated the existence of one of the causes of the phenomenon. Hunter caused a barrel full of earth, and in the centre of which he had placed some beans, to revolve round a horizontal axis; when this rotatory motion had continued for several days, he examined the beans and found the direction of the roots parallel to the axis of rotation. Knight fixed some beans in a suitable manner upon the periphery of a wheel, which he caused subsequently to revolve for a considerable period of time, taking care to keep the beans constantly moistened: in one experiment the revolving wheel was placed in a vertical, in another in a horizontal, position. Knight found that in the former case the roots of the young plants were directed towards the circumference, and the stalks towards the centre, of the wheel; whilst in the latter case, the roots and stalks were directed obliquely, the roots, however, still inclined towards the circumference of the wheel.

These experiments show that the direction of the stalks and roots of plants is under the influence of gravity; the oblique position of the roots, in the second experiment, is owing to the contending influence of two forces, viz., the centrifugal force, which tends to place them in the horizontal, and the force of gravitation, which tends to place them in the vertical, position.

To account for the facts revealed by Hunter's and Knight's experiment, it is obviously necessary to assume—1, that the new parts of the young plant are in a state of greater or less fluidity; 2, that the divers parts of the young plant are of different density; 3, that the densest parts of the young plant incline towards the roots, at least during the first period of germination.

Dutrochet, without denying the influence of gravity upon the usual direction of the roots and stalks of plants, maintains that there exists another cause for this phenomenon, viz., the unequal development of the cellular system of the stalk and roots, and the different degree of turgescence produced in the cells of this system by endosmosis.

We know hardly anything of the physiological action of light upon animals. Edwards has shown that the development of the eggs of frogs, and subsequently of the tadpoles, progresses more rapidly in the sun than in dark places.

The colours of animals appear the more intense and lively in proportion to the intensity of the light to which they are exposed. Some physiologists maintain that the action of the solar rays increases the cutaneous exhalation of carbonic acid in animals; but, as we do not know to which of the solar rays we have to ascribe this effect, we are unable to attribute it positively to the chemical action of those rays, however probable this appears otherwise.

The action of light upon plants is better known. The respiration of the plant, in other words, the decomposition of the carbonic acid operated by the green parts, the fixation of the carbon, and exhalation of the oxygen, proceed only under the influence of the solar light: in the dark, on the contrary, the plant absorbs oxygen and emits carbonic acid. It is in the light that plants acquire their tints, and that their tissues contract and harden; whilst, in the dark, they lose their colour, and their stalks become lengthened and softened. The action of intense artificial light is similar to that of the sun, although, of course,

much feebler. The only known fact calculated to throw some light upon this singular action of the sun is that revealed by Daguerre's invention: in taking images with the Daguerreotype it has been observed that the green parts of plants and, generally speaking, all green substances are not, like the other parts, reproduced upon the plate. Now, as it is clearly and fully established that the formation of images by Daguerre's process is owing to the action of the chemical rays of solar light, we can only account for the non-reproduction of the green parts by assuming that these parts absorb the chemical rays of the sun entirely. This would lead to the conclusion that the production of the green matter in plants, and the extraordinary property, with which this matter seems endowed, to decompose carbonic acid under the influence of light—absorbing the carbon and exhaling the oxygen—are dependent upon the chemical action of the solar rays. At all events, it results from some experiments made by Draper, that it is principally under the influence of the luminous rays, properly so termed (the yellow rays), that the green matter of the plants decomposes carbonic acid. This subject offers a wide field for research and experiments.

The roots of certain plants have a tendency to shun the light, whilst those of others, on the contrary, eagerly seek it. The roots of several plants of the family of the *Cruciferae* are instances of the former, those of the *allium cepa*, of the latter, tendency.

According to Dutrochet, the structure of the internal layer of the bark of the roots is different in roots that shun, from that in those which seek, the light; and it is to this difference in structure that Dutrochet ascribes the opposite tendencies. Generally speaking, the largest cells in the bark of the roots of young plants are found in the central layers; and they go on decreasing in size both to the external and internal faces of the bark; but in some cases this decrease is less marked in the outer, in others in the inner, layers. The influence of light and solar heat causes the plant to perspire and the cells to give up the water which they contain; hence it results that the roots seek the light in all cases where the internal layers of the bark are of greater density than the external, and that, on the other hand, they shun the light in all cases where the external layers are of greater density than the internal.

We come now to the influence which heat exercises upon organized living bodies.

A suitable temperature may be considered one of the essential conditions of life. The physico-chemical phenomena of living bodies are produced only within certain limits of temperature, which are likewise the limits of animal and vegetable life.

We know that the various actions of contact take place only at a certain temperature.

The fecundation and germination of vegetables take place only at a certain temperature, and the actions of contact play a considerable part in this mysterious phenomenon.

Edwards found that frogs placed in river water of 22° Fahrenheit, lived eight hours; in water of 50° Fahrenheit, six hours; of 60° Fahrenheit, two hours; of 71° Fahrenheit, from thirty-five to seventy minutes; of 89° Fahrenheit, from twelve to thirty minutes; in water of 107° Fahrenheit, death ensued instantaneously.

The great influence which slight variations of temperature exercise on the life of the frog cannot be attributed to any supposed difference in the quantity of air held in solution by the water at different temperatures. It is well known that the proportion of air dissolved in the water varies very slightly indeed with the different seasons of the year.

Edwards has found that the amount of air respired by frogs is the more considerable the higher the temperature of the medium in which they find themselves placed, so that elevation of temperature renders the quantity of air which the water holds usually in solution insufficient

for the respiration of the animal, even though it be constantly renewed.

Frogs, accordingly, live immersed in water of a very low temperature only; placed in water of a higher temperature, they come to the surface and respire the air of the atmosphere. Fishes present analogous phenomena: placed in water containing a certain amount of air in solution, and precluded from contact with the atmosphere, they continue to live the longer the lower the temperature of the water.

A torpedo placed in water of 82° Fahrenheit died speedily, giving a series of strong shocks; the same torpedo had been kept alive a long time in cold water, giving only rare and feeble discharges.

The relation thus found to exist between the respiration of animals and the temperature of the medium in which the animals exist forms a new proof of the chemical nature of the respiratory functions.

Man and the mammifera in general are capable of bearing a temperature much higher than their own. Tillet and Duhamel saw a young girl remain for twelve minutes in a kiln heated to 262° Fahrenheit. Delaroche and Berger placed rabbits, cats, and other vertebrate animals in an oven heated to from 132° to 149°; the animals died in a few minutes. The results of a series of experiments has led these observers to arrive at the conclusion that a temperature of 113° Fahrenheit in a dry atmosphere is near the extreme limit at which vertebrate animals can exist. It would accordingly appear that man alone can bear a higher temperature. Dobson cites the case of a young man who remained twenty minutes in a kiln heated to between 190° and 210°; when he came out of the kiln his pulse marked 164 per minute instead of 75, which was the usual number with him. Berger remained seven minutes shut up in an atmosphere of 228° Fahrenheit; Blagden bore a heat of 260° Fahrenheit.

But the matter is very different if the air is saturated with aqueous vapours. Berger could only remain twelve minutes in a vapour-bath of which the temperature was raised from 113° Fahrenheit to 125° Fahrenheit. In a water-bath man cannot even bear the temperature which he is capable of enduring in a vapour-bath.

How far is the temperature of animals modified by the divers degrees of heat to which they are exposed? As far as the ordinary variations of temperature, dependent upon climates and seasons, are concerned, the heat of the human body is not sensibly modified by them. Davy's numerous experiments give only slight differences in this respect. Franklin observed that his body was 95° Fahrenheit, whilst the surrounding air was at 99° Fahrenheit. This fact led to the conclusion that animals with warm blood possess the faculty to remain at a lower degree of heat than that of the surrounding medium. Delaroche and Berger observed that the temperature of the body of one of them who had remained for eight minutes in an atmosphere of 186° Fahrenheit had risen by 9°. The results of numerous experiments made upon mammifera and birds proved to these observers that the exposure of animals to a dry and hot air induces a rise in their temperature, which, however, can never exceed from 12° to 14° Fahrenheit, without causing death.

It is easy to account for the effects of the external temperature upon the heat of animals. The formation of the aqueous vapour, which constantly escapes through the skin of an animal, acts as a permanent cause of refrigeration; this explains why the temperature of animals does not rise so much in hot and dry air as in an atmosphere saturated with aqueous vapour. There exists thus in the animal a continual source of heat and a constant cause of refrigeration; and its temperature remains almost stationary, notwithstanding the variations surrounding in the temperature of the surrounding media (although the latter may happen to be much hotter or colder than the temperature of its own body), since the cause of refrigeration

acts more energetically in proportion as the external temperature is higher, and *vice versa*.

A very marked difference is observed in the refrigeration of animals, according as the surrounding atmosphere is calm or agitated. When the air is calm and at a lower temperature than that of our own body, we lose heat by evaporation, by the contact of the air, and by radiation; with respect to the latter (loss of heat by radiation) the presence and nature of the gas, and the agitation, are without marked influence upon it; but the loss of heat by evaporation, or by contact of the air, is considerably increased by agitation of the latter. Thus Parry states that he frequently bore a cold of +0.14 Fahrenheit without being painfully affected by it, when the air was calm; whilst he felt serious inconvenience from a cold of +20°.012 Fahrenheit, when accompanied by even a light breeze. The surgeon of Captain Parry's celebrated expedition reports that the sensation of a cold of -50°.998 Fahrenheit, in calm air, was comparable to that produced by a cold of +0.14 Fahrenheit, accompanied by a breeze. From this observation it would result that a certain agitation of the air produces a sensation of cold equivalent to the effect of a refrigeration of -51°.012.

DUMAS ON ORGANIC CHEMISTRY.

No. XXVII.

(Continued from page 450.)

THE MILK OF THE DIFFERENT MAMMIFERE.

Milk of Woman.—The milk of the human female, of which the composition has been already given, resembles that of the cow in its physical properties: its density is nearly the same; it varies, according to M. F. Simon, from 1.030 to 1.034. It is invariably alkaline at the moment of drawing it, and preserves this property for several days. It, however, differs from the milk of the cow, in the difficulty experienced in precipitating its caseum by acids. Rennet coagulates it, not in consistent clots like those formed in cow's milk, but rather in detached flakes.

The following are some analyses of this milk, due to M. Simon. The first gives the mean of fourteen analyses made successively upon the milk of the same woman; the second was drawn from a female, thirty-six years of age; whilst the third belonged to a mother, aged twenty:—

	I.	II.	III.
Water	883.6	894.0	898.0
Butter	25.3	38.0	28.8
Caseine	34.3	34.0	32.0
Sugar of milk and extractive matters ..	18.2	40.5	36
Fixed salts	2.3	1.8	0

The analyses of MM. Pfaff and Schwartz give to human milk 0.4107 per cent. of salts, composed as follows:—

Phosphate of lime	0.25
Phosphate of magnesia	0.05
Phosphate of iron	0.0107
Phosphate of soda	0.010
Chloride of potassium	0.03
Soda arising from the decomposition of the lactate	0.03

0.4107

Milk of the Ass.—This milk is often acid; yet it greatly resembles human milk in its composition. Its density varies from 1.023 to 1.035; according to M. Peligot, it is comprised between 1.030 and 1.035. It ferments with great readiness.

Mare's Milk.—This is chiefly distinguished from other kinds of milk by its richness in lactose; it is, moreover, poor in fatty matter, for, according to Van Stiptrian, Luiscius, and Bondt, it contains but four-fifths per cent. of this principle. It is with this milk that the Tartars produce their alcoholic liquid; and, according to its composition, it should be very suitable for that purpose.

Milk of the Goat.—The density of goat's milk is about 1.036. It possesses a peculiar rank odour, which is much more marked in the dark-

coloured animal than in the light one. This odour is communicated to the butter. The coagulated caseum is hard and consistent.

Milk of the Sheep.—This is very rich in solid matters. Its density varies between 1.035 and 1.041; it is less fluid than cow's milk; it has an agreeable odour and taste. According to Stiptrian, Luiscius, and Bondt, it contains:—

Water	63.2
Butter	6.8
Caseum	15.8
Sugar of milk	4.2
Cream	11.5

100.0

Milk of the Bitch.—It is very thick, possessing a disagreeable animal odour, and a slightly saline, nauseous taste, quite devoid of sweetness. This milk contains an extraordinary quantity of solid materials, the proportion of which is sometimes found so high as 30 per cent. It is converted into a thick consistent mass by heat. Its serum, when evaporated *in vacuo*, yields to boiling alcohol a matter which becomes concrete like urea under the influence of nitric acid. Its butter appears to be devoid of all volatile fatty acids. It commonly crystallizes in nipple-shaped prolongations.

Preservation of Milk.—In a state of nature, milk is ordinarily consumed upon the spot; but, when the consumption of a locality is much below its production, it becomes necessary to have recourse to certain methods of preserving it. These means may be classified under three heads:—1. The preservation of the milk in its natural state; 2. The conservation of the immediate principles of the milk—a plan which enables us to prepare afresh the emulsion which constitutes it; 3. The manufacture of cheeses.

We have already seen that M. Gay-Lussac has succeeded, by means of ebullition, in preserving the milk for a very long time, even during the heats of summer. This plan is not, however, applicable on a large scale. It has been proposed to evaporate the milk to dryness; but this proceeding is also difficult of application, where the quantity of milk is large; moreover, the powder, which we thus obtain, quickly grows rancid, and no longer makes an emulsion when brought into contact with water.

M. Appert preserves the milk, in its natural state, in full bottles, which are to be well stoppered and subjected to a temperature of 100° C.; but the agitation caused by its transport always separates a portion of the butter, which will be found swimming on the surface of the liquid.

MM. Grimaud and Calais reduce the milk to a dry paste, by passing through it a current of cold air, which removes from it all its water. This dry paste, on being mixed with a certain quantity of water, reproduces the original milk.

M. Braconnot has proposed two other plans which altogether differ from the foregoing. Some newly formed cheese is to be acted on by boiling water, and for every 500 parts of cheese we are to add 12 parts of bicarbonate of potash, after which the whole is to be dissolved in a further quantity of boiling water. This solution is to be concentrated in a water-bath, taking care constantly to stir it. When it begins to present a gelatinous appearance, it is to be thoroughly dried. The product, thus obtained, may be preserved for any length of time, and is capable of being employed to great advantage at sea.

The second process, invented by the same chemist, consists in coagulating 3 kilogrammes of milk by hydrochloric acid, at a temperature of about 15° C. We then express the coagulum, and add to it 10 grammes of crystallized carbonate of soda, dissolved in a small quantity of water, so as to obtain about half a kilogramme of a thick, consistent substance. To this species of jelly we are to add a third of its weight of pulverized sugar. The artificial cream, thus obtained, answers perfectly for all culinary purposes, in cases where it becomes impossible to procure fresh milk.

Cheeses.—In those places where the production of milk is greatly beyond the requirements of the immediate population, a part of this liquid is employed in making cheeses. Under this form it becomes especially suitable for exportation: for, not only is the caseine—that important nutritive element of the milk—found concentrated in the cheese, but it exists there in a state very favourable to its preservation. Thus, the manufacture of cheeses constitutes, in some countries, an important branch of commerce, of which we will now endeavour to give some idea.

The successive operations into which this art is divided consist, in the first place, in coagulating or curdling the milk; then, in dividing or breaking the coagulum, to facilitate the separation of the whey; and, lastly, in strongly expressing it by means of presses. To complete the formation of the cheese, we have merely to salt or season it, and then to keep it for some time in cellars, where it undergoes a species of fermentation.

We usually employ the milk of the cow in the preparation of cheeses; that of Roquefort is, however, made with a mixture of goat's and sheep's milk. There is no doubt but that the nature of the milk must exercise some influence over the qualities of the cheese; yet this influence is not so marked as one might at first sight be led to believe. That which chiefly modifies the properties of the cheese, is the mode of manufacture, which varies greatly in different localities. In this respect, we may remark that variations which, appear but slight, in the manner of preparation of the cheese, are in reality capable of giving to the products essentially different qualities. In a scientific point of view, it becomes a difficult matter to render an account of the cause of these variations; we may even affirm that, in the actual state of science, we are totally ignorant of the character of the modifications which the caseine must undergo to become transformed into cheese. Hence, we may conceive that the operations of which we have been speaking are, in the absence of theoretic indications, entirely based on rules deduced from experience.

The following is the course usually adopted in the making of cheese. We commence by heating the milk to about 28° or 30° C. The water-bath is, perhaps, the best medium for effecting this operation. We then add the rennet. This is the name given to the peculiar ferment destined to effect the coagulation of the milk, and which is prepared, as already stated, from the stomach of the newly-born calf. This agent may be employed under the form of infusion, or in its simple state, by placing it in a small bag, which should be allowed to remain in the milk for a certain time. From eight to twelve grammes of rennet are sufficient to coagulate ten litres of milk. A contact of one or two hours is necessary to obtain a complete coagulation.

When the clot is well formed and sufficiently firm, we are to break it, so as to separate the whey. This operation is usually performed by means of a three-bladed knife. The ruptured coagulum soon accumulates at the bottom of the vessel, when we are to pour off the whey and collect the cheese in a sieve. After having allowed it to drain, it is put beneath a press or under a board loaded with weights. About half an hour afterwards, the cheese is to be removed, broken into small pieces, and ground into fine particles by the aid of a mill. The homogeneous pulp, thus obtained, is once more subjected to a graduated compression, which lasts from twelve to twenty-four hours. In some localities, where they wish to give a greater degree of hardness to the rind, the compressed cheese is *scalded*, by steeping it for the space of a couple of hours in a vessel filled with hot whey or water, after which it is again subjected to the action of the press.

The operation of salting consists in plunging the cheese, when pressed and surrounded by a proper cloth, into some strong brine, in which it is to remain for the space of several days. At other times, for the purpose of salting the cheese, its sur-

face is carefully covered over, and the sides well rubbed with pounded salt, taking care to turn it from time to time. When we consider the operation to have been continued long enough, which usually happens at the end of about ten days, the surface of the cheese is to be washed with hot water or whey, and it is then to be put upon a board to dry.

Having dried the cheeses, they are carried to the cellar or storeroom, and there ranged on shelves or tables. Here they are left for a longer or shorter time, so as to undergo a species of fermentation, the progress of which is slackened by the salt with which they are impregnated. When they have acquired their proper taste and qualities, they are sent to market for use.

Such are the different operations comprised in the manufacture of cheeses. As might be imagined, these stages undergo certain modifications according to the nature of the cheese which it is intended to fabricate. The process which we have just been describing is very similar to that employed in making the cheese of Gruyères. We need merely add, that the coagulum, when properly prepared, is heated in a stove until it attains a temperature of about 33° C., after which it is subjected to pressure, as already described.

Parmesan cheese is made with skimmed milk; its paste is ordinarily coloured with saffron.

The cheese of *Brie* is manufactured with unskimmed milk. This is a rich cheese, of excellent quality, when well prepared, but which presents the inconvenience of not keeping long.

The fabrication of *Dutch* cheese is different: it is made cold, and with the entire milk.

The qualities of the cheeses of *Chester* vary according to the quantity of cream which they contain. In some dairies, they separate a portion of the cream formed during the night for the purpose of making butter, and add the milk thus skimmed to what is drawn in the morning; while, in other places, they use the whole cream, or withdraw any portion of the milk which has been skimmed.

The cheeses of *Roquefort* are made with a mixture of goat's and sheep's milk. Their mode of manufacture differs but little from those which have been already indicated. They have, however, this peculiarity: that they are left for a certain time in caves, which are formed in the calcareous rock surrounding the village of Roquefort, and in which are found numerous fissures giving passage to currents of cold air. The temperature of these caves is consequently remarkably low. Chaptal observed, on the 21st of August, 1787, that a thermometer, marking in the shade 23° R., descended to 4° above 0° after a quarter of an hour's exposure in the vicinity of one of these rapid currents.

Eggs.—*Their Nature and Composition.*—The egg, the product of conception of the bird, is composed of three parts: the *shell*, a hard covering, lined internally by a membrane; the *white*; and the *yolk*.

The *shell* is ordinarily colourless; sometimes, however, it offers varied tints, among which grey is that most frequently observed. Shells are not impermeable; they are studded with pores which give passage to the air. The oxygen of this air undoubtedly plays an important part in the chemical phenomena which accompany the development of the young bird.

Vauquelin and Proust have analyzed the shell of the egg of the chicken, which, according to these chemists, contains:—

	Vauquelin.	Proust.
Carbonate of lime	89.6	97
Phosphate of lime with a little phosphate of magnesia	5.7	7
Animal matter containing sulphur	4.7	2

The shell is lined internally by a thin membrane formed, according to Vauquelin, of coagulated albumen; it constitutes about a five-hundredth part of the weight of the egg, and leaves, on incineration, a small quantity of ashes formed of phosphate of lime. At the large extremity of the egg, it is detached from the shell for a certain extent, and the cavity thus formed

is filled with air which, if we may rely on the experiments of M. Bischoff, is even somewhat richer in oxygen than the external air itself.

The *white* of the egg may be said to consist of a somewhat concentrated solution of albumen, contained in very thin cellular bags, but which are sufficiently resistant to hold this liquid, and which give to it a peculiar gelatinous aspect. The outermost cells enclose a less concentrated solution of albumen than those which surround the yolk. White of egg contains from 12 to 13.8 per cent. of albumen. It coagulates at a temperature of 75° C. When mixed with water, we never obtain a perfectly clear solution; for the membranes, being torn by the effect of the agitation, and being of themselves naturally insoluble, invariably render the liquid cloudy.

For the same reason, the albumen of the white of egg can be filtered only with great difficulty. But to give it a perfect fluidity, and to obtain a clear solution, we have merely to add a few drops of potash, which will at once dissolve the membranes.

White of egg almost always contains soda and chloride of sodium: we also find in it some traces of extractiform matter, soluble in alcohol.

Proust has determined the nature and the proportion of the inorganic matters contained in white of egg. The following are the results at which he arrived by incinerating this substance and analyzing the ashes:—

	I.	II.	III.
Sulphuric acid	0.29	0.05	0.18
Phosphoric acid	0.45	0.46	0.48
Chlorine	0.94	0.93	0.87
Potash and soda, partly in the state of carbonates	2.02	2.83	2.73
Lime and magnesia (ditto)	0.30	0.25	0.32

The *yolk* occupies the central part of the egg; it is separated from the white by a membrane which is attached to the outermost cells by two ligaments, called *chalazæ*. It is a true emulsion, formed by an aqueous solution of *vitelline*, and holding in suspension a peculiar oily matter. To isolate this latter principle, it is customary to torrefy the yolks, which have been previously coagulated by heat, until they acquire an oily appearance, and then to express them. We may thus extract from each yolk about three grammes of a thick oil, having a reddish-yellow colour, and which congeals under the influence of cold. It possesses a peculiar odour and an agreeable taste. As it almost always contains some debris of foreign animal matters, it turns rancid very rapidly. To purify it, and preserve it for any length of time, it is necessary to dissolve it in ether. The particular nature of this oil is not yet known. We are merely aware that, like cerebral matter, it contains sulphur and phosphorus—a fact which explains the difficulty of perfectly incinerating it. Very recently, M. Gobley has proved that the phosphorus is contained in this oily matter in the form of phosphoglyceric acid—a combination of phosphoric acid and anhydrous glycerine, recently discovered by M. Pelouze. M. Gobley has, moreover, found in the yolk of egg some oleic and margaric acids.

According to M. Lecanu, the yolk of egg should also contain about a third per cent. of a crystalline, non-saponifiable, fatty matter, fusible at 154° C., and which he regards as identical with cholesteroline. As to the vitelline, it has been already described.

By incinerating the yolk of egg with nitrate of lime, Proust succeeded in determining the proportion of inorganic matters which it contains. The following are the results he deduced:—

	I.	II.	III.
Sulphuric acid	0.21	0.06	0.19
Phosphoric acid	3.58	3.50	4.00
Chlorine	0.39	0.28	0.44
Potash and soda, partly in the state of carbonates	0.50	0.27	0.51
Lime and magnesia (do.)	0.68	0.61	0.67

OBITUARY.—On the 9th inst., at Bath, Joseph Kearsley, Esq., M.D., formerly deputy-inspector of the Ordnance Medical Department, aged 82.

ORIGINAL CONTRIBUTIONS.

ON THE PHYSIOLOGICAL AND PATHOLOGICAL CAUSES OF SUDDEN DEATH IN CONNECTION WITH THE VASCULAR OR CIRCULATORY SYSTEM.

By M. W. HILLES, Esq.

(Continued from p. 451.)

Part 1.—Cases of sudden death produced by a lesion or morbid alteration of some portion of the nervous system.

Part 2.—Cases of sudden death produced by impressions made on the nervous system, or some part thereof, without lesion or morbid alteration.

PART I.

ON CASES OF SUDDEN DEATH PRODUCED BY A LESION OR MORBID ALTERATION OF SOME PORTION OF THE NERVOUS SYSTEM.

When we reflect on the great importance of the cerebrum, as well as all parts of the nervous system, we are surprised at the amount of injury that may be inflicted on, and the extent to which disease may spread in, this organ, with comparative impunity.

Numerous cases are on record where extensive injuries have occurred to the cerebrum, and even considerable portions of its substance destroyed and removed, without causing any serious symptoms to the patient.

Even a brief detail of these cases would occupy many pages: it will be sufficient for our purpose to mention some of the particulars of one of those remarkable cases:—

"In the year 1843 there lived in the quarter San Pablo, at Mexico, the family of an officer of cavalry. A son of this man, a boy of about twelve years of age, was one day rashly playing with a loaded horse-pistol, when, by some accident, the pistol was discharged; the bullet struck the young child, traversing his head from temple to temple, and afterwards buried itself in the plaster of the opposite wall.

"The child survived until the twenty-ninth day after the accident, and was, in the interim, seen by many Mexican and foreign physicians. He was lively and cheerful, except during the dressing of the wounds, manifesting the possession of all his mental faculties.

"After death it was found that the cranium had been perforated about 1½ inch above the external orbital process on each side; the anterior part of both hemispheres had been traversed by the ball; in front of the canal, occasioned by its passage, there was a layer of cerebral tissue, six or eight lines in thickness, and the grey matter above it was also intact."—*Medical Gazette*, vol. 1, sess. 1845, p. 38.

Sir Charles Bell states on this subject:—

"Whole masses of the brain may be destroyed by disease, or actually removed with impunity, that is to say, without any immediate influence on the mind, or on the power of motion or of sensibility; yet the very slightest impression on the brain will, on the instant, deprive the individual both of sense and motion."—*On the Nervous System of the Human Body*, by Sir C. Bell. Edinburgh, 1836; p. 208.

This fact, at first view, appears to oppose the opinion that the brain is the organ of the mind, but it is equally opposed to this organ being of any use whatever in the animal economy.

Although whole masses of the brain have been lost with impunity, these cases are but exceptions to the rule, and are to be observed only in certain situations, where the tissue of the brain is not of a fibrous character, as on the surface and in the anterior lobes, where, in fact, the organ does not possess that material structure apparently so necessary to the exercise of the cerebral functions.

In all cases where the fibrous structure of the brain, or those bodies, such as the corpus striatum, optic thalamus, &c., which exert a peculiar influence in the development of its functions, have been injured or destroyed, corresponding symptoms have been present.

The brain must be regarded as a compound

organ, composed of a number of peculiarly shaped bodies, some of which minister to special functions, whilst all are necessary to the complete perfection of the organ itself.

Its external surface appears to contribute to such functions as a secreting structure, which eliminates that which is designated as the nervous fluid, and which, by its passage through the various bodies in the interior of the organ along its fibrous tissues, and ultimately conducted by the nerves to its destination, produces those manifestations of sense, motion, or sensibility, which indicate the presiding influence of a sentient structure.

A loss, therefore, of a portion of this may occur without any serious result: it is but the loss of so much secreting substance, whose office may be carried on by the remaining tissue, as a portion of the liver, lung, or other organ may be destroyed without any serious injury to the functions performed by these structures.

Any injury which affects the whole mass of brain, simultaneously, is on the contrary attended with serious symptoms: the pressure of a depressed portion of bone, a clot of blood, or even the pressure exercised by the finger, is sufficient to destroy all its functions, mental or otherwise, the patient, in many instances, recovering from, or relapsing into, a state of unconsciousness, according as the pressure is removed or applied.

Considerable extravasations, however, occur in some situations in the brain without producing very urgent symptoms, as into the corpus striatum, optic thalamus, lateral ventricles, &c.; at first the pressure exercised by the extravasated blood causes apoplectic symptoms, but after some little time part of the blood and portions of the brain become absorbed, so as to relieve the remainder of the organ of pressure and enable it to resume its usual offices so far as these are compatible with the permanent injury done to the cerebral tissue.

It is far otherwise with regard to those parts of the brain which, partaking of the fibrous or other more highly organized character, are more actively engaged in the elaboration or transmission of that nervous fluid, on the due supply of which all the functions of life depend.

Here the smallest extravasation usually proves immediately fatal, that is, in the course of a very few minutes after the rupture of the vessel occurs. I have already stated the situation of the pons varolii to be most unfavourable to the patient, in consequence of the various fibres of the brain, both cerebrum and cerebellum, being collected here; it frequently occurs that, in consequence of some mental or other emotion, a rupture of the basilar artery takes place, followed by immediate death. Several cases are recorded of sudden death occurring during the act of coition from this cause. Can this artery be more immediately affected during this act, as it chiefly supplies the cerebellum with blood?

The same observations apply to extravasations of blood about the upper extremity of the medulla oblongata and in the cerebellum. As this latter presides over the animal life of the individual, the suddenly fatal nature of such extravasations is easily accounted for.

INTERMITTENT FEVER IN LOWER NORMANDY.

By W. G. DALGAIRNS, Esq., Surgeon to the Strangers' Hospital, Havre.

To compare the diseases of one people with those of another, must always throw some light upon their cause and mode of treatment; that the same malady will affect individuals of one nation differently from those of another is now pretty generally acknowledged: for the *rational* we must look either to the constitution of the person, or climate of the place. A disease which appears for the first time in a country is more virulent and fatal to the inhabitants than when it has existed for centuries, the system becoming, in some measure, accustomed to its influence, and the once being affected by it often ameliorates, if not prevents, its recurrence. The African

frequently falls a victim to an attack of smallpox, but lives a healthful life in Sierra Leone, so fatal to the European. The inhabitant of a malarious district suffers less from ague than the stranger who pays merely a casual visit; a knowledge of his fact has led to the recommendation by the French General Mounet, of stationary garrisons in these districts, the troops becoming, as it were, acclimated to the air, much in the same way as the opium-eater to the juice of the poppy.

On the coast of Normandy, bordering the Seine, here is a low sandy tract of open country, once entirely covered by water, but now only partially so during the heavy rains in the winter. This extends from the town of Harfleur to that of Havre, a distance of about five miles; here ague is so common that few escape the disease, and one house especially, has the reputation of being haunted, from the fact that the families who have inhabited it have one by one died off, and the landlord can only obtain a tenant by letting his property at a rent much below its value.

Having had the care of about 1000 men, employed on the Rouen and Havre Railway, which passed through this tract of land, I have collected some facts which perhaps may prove interesting to those who take interest in this disease. The workmen were chiefly composed of British, French, Belgians, and Germans, and employed under ground making the tunnels, or on the road where they were surrounded by marshes and bogs, and in the summer exposed to a hot sun without a tree in the neighbourhood to shelter them.

It has been frequently observed that the diseases which attack persons inhabiting malarious districts occasionally take an intermittent form; this was well exemplified in some of those men who were employed day and night in the formation of tunnels, many of whom became affected with a disease which had all the symptoms of typhus, but was accompanied by profuse perspiration, recurring at the same hour daily, or every second day. As the cases are interesting, it may be as well to give them.

1. John Biselle, native of Switzerland, aged thirty-two, a sober, steady man, was admitted into the Strangers' Hospital, February 10, 1847, complaining of headache, noise in his ears, flashes of light in the eyes, bleeding from the nose, and pain in all his limbs and in his abdomen. He was taken ill a week before his admission with shivering, followed by fever, loss of appetite, thirst, &c. His pulse, on his admission, was quick, about 100; his respiration 40 in the minute; his abdomen was tense and tympanitic; his bowels not opened for one day before his admission; tongue covered with a dry, brown fur; his teeth with sordes; rhonchus and sibilus audible over the whole chest, before and behind; sputa thick and viscid, light coloured; skin not so dry, except about the middle of the day, when he perspired profusely for some hours.

Rx. Ammoniac carb., gr. x.; ant. pot., tart., gr. 1-6; decoct. serpentariae, ʒj., 4tis horis; and arrowroot, beef-tea, &c., as diet.

He gradually got better under this treatment; the sweating being less profuse each day, until the 30th, when he was taken with a perfect fit of ague in all its stages, which a few doses of quinine cured.

2. André Seigneur, a Bavarian, aged thirty-five, was admitted into the Strangers' Hospital, Dec. 6, 1846. He stated that he had been ill about a week, and that his illness had commenced with shivering. He complained of great headache, and pain in the abdomen and limbs; his tongue was covered with a dry brown fur, and his teeth with sordes; his skin was hot and dry, except every second night, when he perspired so profusely that his shirt, in the morning, was as wet as if it had been dipped in water; his bowels were opened no less than five or six times a day; his pulse 80; respiration 20.

Rx. Ammoniac carb. gr. x.; tinct. opii, m. x.; aqua, ʒj., 4tis horis.

As the bowels still continued to be loose,

Rx. Tinct. opii, m. xxx.; decoct. amyli, ʒj. i.; f. inject., was ordered after every motion.

For fourteen days the diarrhoea continued, on an average, from five to eight times a day. The same diet as for Biselle was also ordered, and sponging with vinegar and water every morning and night.

He continued to improve up to the 30th of December, when he had an attack of tertian ague, which was also soon cured under the use of quinine.

In other cases, there were perfect fits of ague, but accompanied with such excessive continued pain in the head—worse, it is true, shortly before and during the fit—that the patients were unable to bear exposure to light, or even sit up in their beds. In one man, especially, of the name Austin, the pain was so excruciating that he implored of me to bleed him; and, as I strenuously refused to do so, he consulted another medical man, and persuaded him to take some blood from his arm; the consequence was, that all the symptoms were aggravated, and the man had an attack of hemiplegia, there being weakness and numbness of one side. He, with another man of the name of Marquis, had frequent hematemia during the cold stage. The fits continued in both cases for six weeks; and, although quinine at one time and arsenic at another were administered freely, still the sweating continued regularly at the same hour daily (the other stages having disappeared under the above-mentioned treatment), and it was not until they had both left the country that they became perfectly cured.

In another case, a woman named Clarisse, medicine of any sort had little effect; but change of air cured her directly. Shortly after her return she had a miscarriage (being then in the second month of her pregnancy); the hemorrhage attending it was so great as to cause a succession of fainting fits, which nearly carried her off. Two days afterwards the ague returned, and could not again be got rid of until she had taken a second trip.

It is strange that in the French there is a great intolerance of anything like a large dose of quinine; so much so that some prefer allowing the disease to take its course, rather than induce the symptoms of gastritis which in them it frequently occasions.

The treatment generally adopted in this hospital is quinine in doses of ten grains a few hours before the attack is expected; and for the pain in the head and region of the spleen the application of blisters. During the cold stage, heat to the surface, and in the hot warm drinks to induce sweating. Frequently a full dose of laudanum tends to shorten the fit.

Among the French this form of giving arsenic is frequently of use:—Aqua ferventis, Ojss.; acid, arsenios, gr. ij. Boil for a quarter of an hour, and when cold give a table-spoonful every morning. They also induce vomiting during the fit by giving pulvis ipecac. simpli, gr. xx.; aqua calide, Oj.

For the diet, the most nourishing food as well as the easiest of digestion, such as arrowroot, jelly, beef-tea, and sometimes wine.

DEXTRINE BANDAGE IN COMPOUND FRACTURES.

Finding the application of this bandage in simple fracture so beneficial, I have been led to make use of it in the compound also: thus, a dextrine bandage is to be applied in the usual way on the sound limb, and when dry removed by cutting it down both before and behind, being careful behind only to cut through the dextrine, leaving the under bandage so as to form a hinge by which it may be opened and shut; but in the front both bandages are to be cut through. This is to be applied to the broken limb, and kept together by means of straps.

The object is to be able to open the bandage so as to dress and keep clean the wound, and to close it again without moving the limb; and if care be taken in the cutting it will sit as close as if applied to the broken limb itself. A many-tailed bandage and oil-silk may be used, and removed when soiled without altering the position of the fracture.

CANCER OF THE LIVER AND STOMACH; POST-MORTEM APPEARANCES; AND OBSERVATIONS.

By H. EVANS, Esq., Pwllheli, North Wales.

An unmarried man, aged thirty-two, by trade a miller, of temperate habits, had always enjoyed good health till two months prior to his application, when his illness came on, as he supposed, from having injured himself in carrying a heavy load upon his back.

When I saw him he was able to take a little exercise, but compelled in walking to stoop to ease his back; the pain was limited to a small space over the angles of the false ribs on both sides, which was so violent as to prevent him from getting any rest, either by day or night.

About a fortnight afterwards he was seen, when he had, in addition, jaundice and ascites, with anasarca of the extremities; he was much thinner, continually suffering the greatest torments in the back, which nothing but enormous quantities of opium relieved; the hepatic region was now examined, and found to be very tender, so much so as to prevent a careful examination being made. He lingered a fortnight longer in the greatest torments, when he died exhausted.

Inspection.—Three quarts of fluid in the abdomen; the liver studded with scirrhous growths of various sizes, the larger ones containing serum; the adhesions between the liver and diaphragm were limited to these growths, which presented the same appearances as so many suspensory ligaments; the organ weighed six pounds. The left lobe was the part perceived to be enlarged; during life it reached below the level of the eighth rib; the gall, hepatic, and pancreatic ducts were unaffected, surrounding the lesser curve of the stomach; for a short distance upon its anterior and posterior wall was a scirrhous mass of a crescentic form; and to examine it the stomach was slit open along its greater curve, when a large ulcer was exposed, the base of which was formed by this mass; the coats of the stomach it had all but perforated; the ulcer was circular and hollowed in its centre, much like two equal halves of a large-sized orange peel; its surface, as well as the cavity of the stomach and all the small intestines, was full of blood, which was traced to a small arterial branch.

The history which this man gave was to the following effect:—That he was quite well until he carried a heavy weight upon his back, for a distance of six miles, and that from that time he had never been well, but from that day he daily got worse. It should be mentioned that the urine, from the beginning, held a large quantity of bile and lithates in solution. Notwithstanding the imperfect sketch which he was able to furnish, yet a correct diagnosis was formed, based upon a deduction of Dr. Geo. Budd, that jaundice, in conjunction with ascites, leads to the supposition of organic disease of the liver; and, this occurring in a person whose habits had not been such as to bring on cirrhosis, the inference would be in favour of cancer.

A farmer, aged fifty, of temperate habits, had always enjoyed very good health till a year before he applied to me. His illness commenced as indigestion; he had pain in the pit of the stomach, especially after eating; flatulency, and occasionally vomiting of his food. He had tried change of air and scenery, and, I should imagine, no trifling stock of physic, without any lasting benefit. When I saw him, he was thin, and his complexion sallow; he experienced nearly constant pain in the pit of the stomach, and invariably confined to one spot, which was so tender as to prevent a careful examination of the part being made; now and then, he had sudden attacks of pain, followed by cold sweats and great depression, and, towards the latter end, constant hiccough. He lingered on for a month, and died fairly exhausted.

Inspection.—Before opening the body a large tumour was felt, and supposed to be the pylorus, which afterwards proved to be the liver in a scirrhous condition; the whole of the anterior surface of the stomach was glued to the upper

surface of the liver; the stomach itself healthy, but the first portion of the duodenum was involved in a large ulcer, which penetrated into the substance of the right lobe for about three inches. The pylorus and the stomach, in this instance, were the parts supposed to be diseased, and, in all probability, in a cancerous state. It may be that the cancerous tumours in the liver were not sufficiently numerous to cause that impediment to the secretion of bile and the passage of blood through the vena cava and porta as to produce dropsy and jaundice; the disease was, however, pretty clear from his rapidly failing strength; the constant pain, always referred to one spot; the constant hiccough—all, taken in conjunction with the cachectic complexion, a peculiar feature in malignant diseases. The

searches of a well-known pathologist leads me to believe the disease to be primarily limited to the stomach and duodenum respectively; that in both instances the liver became secondarily contaminated with cancerous cells, in the same way as pus contaminates the system in purulent phlebitis.

A labouring man, aged thirty-one, of temperate habits, said that his illness commenced with shortness of breath, ascites, and anasarca of the extremities, and shortly afterwards became jaundiced. When I saw him, he was too ill to be tormented with a minute examination; the abdomen was very much distended; the liver could be traced a handbreadth below its usual limits; the urine contained bile and lithates in great abundance. He died comatose four days afterwards.

Inspection.—Liver studded with scirrhous growths, the larger ones containing a large quantity of serum, the organ itself weighing eleven pounds. The diagnosis formed in this case was correct, though it suggested no remedy. How could it? Notwithstanding, it is a consolation to be aware that the less we do the better, except that occasionally an anodyne may be of inestimable service in enabling the dying to settle his worldly affairs, or to receive spiritual consolation.

DE MOTU SANGUINIS.

By J. JACKSON, Esq., Long Clawson, Leicestershire.

If the spleen were a heart, i. e., an auricle and ventricle, in the former of which the gastro-intestinal or mesenteric veins terminated, and if the splenic and portal vein and its ramifications in the liver were an artery like the pulmonary or the aorta, the vessel which takes the blood to and propels it through the capillaries of the liver would be as well understood as the vessel which takes the blood to and propels it through the capillaries of the lungs, or as the vessel which takes the blood to and propels it through the capillaries of the general system. Physiologists understand the pulmonic and systemic afferent vessels, which consist each of a heart and artery; but not the hepatic afferent vessel, which consists of a spleen and vein. They perceive that the pulmonic and systemic afferent vessels produce a constant and rapid motion of the blood through the pulmonic and systemic capillaries; and if the hepatic afferent vessel had consisted, like them, of a heart and artery, they would have perceived that it also produced a constant and rapid motion of the blood through the hepatic capillaries; but, consisting as it does of a spleen and vein, they do not perceive that it produces an *intermittent* and *slow* motion of the blood through those capillaries. Heart and spleen, and artery and vein, are anatomical antitheses, and produce opposite physiological effects:—

Heart + artery = constant and rapid motion of blood.

Spleen + vein = intermittent and slow motion of blood.

If the right auricle and ventricle were a spleen, and the pulmonary artery and its branches a vein in the middle of which the superior and inferior vena cava terminated, there would be an intermittent and slow motion of the blood through the pulmonic capillaries; and if the left

auricle and ventricle were a spleen, and the aorta and its ramifications a vein in the middle of which the pulmonary veins terminated, there would be an intermittent and slow motion of the blood through the systemic capillaries; and if the spleen were a heart in the auricle of which the mesenteric veins terminated, and the splenic and portal vein and its ramifications an artery, there would be a constant and rapid motion of the blood through the hepatic capillaries.

A PIN EXTRACTED FROM THE VAGINA OF A CHILD.

Communicated by J. JONES, Esq., Llanfair, Montgomeryshire.

A fortnight ago, a girl, seven years of age, was brought to me, having the body of a pin protruding from the vagina. It was situated on the right of the clitoris, between it and the meatus urinarius. It was the pointed end that presented itself. Being retained merely by the knob, it was detached with the slightest force. A dose of aperient medicine was administered, and quietness enjoined. In a couple of days afterwards, my patient had suffered no inconvenience, and was quite well. All I could learn of the history of the case was, that she had swallowed a pin a week previously, but that she had felt no ill effect from it until within a few hours of her being brought to me, when, on her suddenly informing her mother that something very much hurt her, the latter found the pin in the situation described.

It may well be asked, what route could the pin have taken in this instance? If, as may be supposed, it traversed and worked its way through the intestines, and perhaps the urinary bladder, is it not astonishing that there were no symptoms of indisposition, or, what we might rather expect, of violent inflammation? And yet can we on no other supposition so satisfactorily account for its appearing where it did.

August 4.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of Aug. 2.

MERCURIAL TREATMENT RECOMMENDED PREVIOUSLY TO THE OPERATION FOR CATARACT.—M. TAVIGNOT remarked that all physicians acknowledged the favourable influence of mercurial salivation upon the progress and cure of keratitis and of iritis—two complications by which the success of the operations for cataract was often endangered. In order, therefore, to prevent the occurrence of these inflammations after couching or extraction, M. TAVIGNOT had in three cases placed the patients under the influence of mercury before the operation, and in all three the results had been extremely satisfactory. Dr. TAVIGNOT was of opinion that the ptyalism should be at the highest towards the fourth or fifth day after the operation, as it was at that period that inflammatory symptoms were most to be feared.

DEVELOPMENT OF THE TESTIS.—M. CHARVET, professor of zoology at the Faculty of Grenoble, forwarded the description of a case of complete inversion of the viscera, recognised during life. This case induced M. Charvet to endeavour to ascertain the cause of the difference of situation of the testes, and arrived at the conclusion that it was due to the large size of the fetal liver, which caused the spermatic glands to occupy in the abdomen different positions on each side, and also occasioned the difference in the length of the spermatic chords.

ACADEMY OF MEDICINE.

Meeting of Aug. 3; M. BEGIN in the Chair.

WATERS OF BALNEUC.—The debate was resumed on this subject; and, after a long and uninteresting discussion, the academy adopted the following conclusion, viz.—That the waters in

question appear to be endowed with some degree of efficiency in the treatment of certain paralytic affections.

PELLAGRA.—Dr. Roussel being on the point of starting for Spain, for the purpose of studying the pathology of this disease, M. Gibert requested permission to make some remarks on the subject. Towards the middle of the eighteenth century, Casal first mentioned the existence in Spain of a special disease, of which an exanthematous eruption was the most striking symptom. Its determining cause appeared to him to be exposure to the sun; and the malady was observed to attack chiefly persons belonging to the lowest orders of society, reduced, by misery and starvation, to a state of cachexy. Indian corn was their principal food. Some years later an analogous affection was observed in Italy by Antonio Pujati, and ascribed to the same causes, although the resemblance of the Spanish and Italian diseases was not detected. About eighteen years since, a physician practising in the neighbourhood of Bordeaux, Dr. Hameau, also recognised a similar affection in the département des Landes, but was not aware of its identity with the Italian pellagra. In 1830 Dr. Brière de Boismont, having observed the disease in Italy, called the attention of the French practitioners to the subject, and considered the origin of the disease to lie in a primary lesion of the nervous system and of the digestive organs. Finally, in 1842, M. Gibert had recorded the first case of sporadic pellagra observed in Paris. This case, in which mania occurred, was soon followed by a second, and both were published by Dr. Roussel, who ascribed the disease to the use of badly-prepared Indian corn. This opinion Dr. Gibert did not coincide in; and he begged to lay before the academy those facts connected with the history of the disease which, at the present day, appeared to be sufficiently demonstrated:—In the first place, pellagra was found to be endemic in those parts of Italy, Spain, and France, where the heat is excessive, the population poor, and food debilitating. Its first appearance was generally in spring. In all cases the malady was one which had its origin in want, and the name of "mal de misère," which it had received in some places, was perfectly justified by its nature. Certain geographical and hygienic conditions seemed, however, to be connected with its development; and towards the observation of these, M. Gibert hoped the academy would direct M. Roussel's attention. Finally, it was desirable that M. Roussel should prolong his sojourn in Spain as far as spring, in order that he might be enabled to study the disease in the early stages of its appearance.

Meeting adjourned at five o'clock.

LA CHARITE.

CLINICAL LECTURE, BY PROFESSOR VELPEAU.

Lipoma, meliceris, and steatoma, are expressions on the precise signification of which surgeons are not of one mind. The tumours characterized by the names have resemblances with each other, and differ also in some respects. Thus, they are generally of small size and very numerous in the same subject; on the head of one person M. Velpeau had counted no less than thirty-nine. The prognosis for the three sorts of tumours is not serious; all finally require to be removed, and each in a particular manner. Formerly they were all commonly called wens; but of late years, in consequence of the progress of morbid anatomy, that designation has been specially applied to lipoma.

A lipoma is a tumour, evidently formed by the agglomeration of fat in hypertrophied adipose cells; it is not encysted, and may exist in all parts of the body where fat is to be met with.

Meliceris, on the contrary, always occupies the skin or the textures immediately subjacent; it is constituted by an obliterated sebaceous follicle in which the secretion has slowly accumulated. When the tumour has been removed, all the elements of the skin are found in the primary cyst, but its contents vary considerably. If the dis-

ease be ancient they may be fluid, and when the cyst has been inflamed, these contents may be increased by the addition of serosity or of pus.

Like the former, steatoma is always found under the skin, but always on the cranium or chest. It is constantly separated from the skin by an inorganic but completely independent sac, in which no vessels can be detected. The matter contained in the meliceris is soft; that enclosed in the steatoma is hard, at least at first. Softening of the tumour begins at its centre, but often shows itself only when the swelling has acquired a considerable size.

Lipoma is, therefore, a soft fatty tumour, without a cyst; meliceris a hard tumour—a sebaceous cyst hypertrophied; and steatoma an encysted round swelling, produced by exudation.

The same operative process should not be employed in these three cases; lipoma and meliceris must both be dissected out, as they adhere very firmly to the neighbouring parts. Steatoma may be removed by an easier method, separated as it is from the vicarious structures by its inorganic envelope, it is easily forced by lateral pressure through a simple incision performed on the surface.

These apparently trifling operations may, however, give rise to dangerous erysipelas; and, as these tumours are none of them capable of assuming a malignant character, we would advise surgeons to refrain from removing them, except when they occasion considerable disturbance of the habits of the patient. It is better to bear with what is only a deformity than to incur the risk of accidents which are not unfrequently fatal.

POLYPUS OF THE RECTUM.—The occurrence of polypus is much more uncommon in the rectum than in other regions, such as the nose, the pharynx, the womb, the ear, or the urethra. We may also add, that in the rectum polypi assume special characters. They often resemble hemorrhoid tumours. They are very vascular, particularly rich in venous blood, soft, and, as it were, fungous to the touch. I have seen other polypi of the rectum presenting a totally different appearance; thus, I found in one man a polypus of the size of the index, supported by a long pedicle, not thicker than a crowquill. The tissue of the tumour was homogeneous, did not present any vascularity, and resembled a piece of skin rarefied by prolonged maceration in water. In another instance I had to do with a globular purple tumour, in which no vessels whatever could be detected. These growths, at first, are only mechanical impediments to defecation, but they may, under the influence of various causes, ulcerate and become malignant, and then they are the seat of pain, both during the motions and during their intervals; hemorrhage occurs, and by the frequency of its repetition weakens the health, and may even endanger the life of the patient. Canterization, excision, and ligature are the three most efficient methods of treatment. The former is rendered difficult by the position of the tumour; excision is far preferable when then growth is not very vascular, in which case we employ ligature.

BATHS MEDICATED WITH CORROSIVE SUBIMATE.—In a very great number of diseases Professor Trousseau recommends these baths—in simple eruptions, such as eczema, when obstinate, and also in syphilitic affections of the skin; again, in that form of rheumatic gout which occupies chiefly the small joints of the hands and feet the baths appear efficacious; for infants affected with syphilis it is the only treatment employed by the professor; in no instance, however long the continuance of the method, has salivation been observed. To each bath are added 15 grammes (3ss) of corrosive sublimate dissolved in 3vj. of spirit, and the quantity is rapidly increased to 30 grammes (5i).

PRESERVATION OF LEECHES.—M. Rodet, an apothecary at Leuzburg, recommends, for the purpose of preserving leeches, to place them for a quarter of an hour in forty-eight ounces of water containing four or five drops of liquid chlorine.

FISTULA IN ANO IN TUBERCULAR CONSUMPTION.—In a recent article in the *Gazette des Hôpitaux* a new cause is assigned to the frequency of fistula in ano in cases of phthisis. The author attributes the accident to the embarrassment of abdominal circulation; this may be true, and, indeed, the enlargement and fatty degeneration of the liver in tubercular disease militate, to a certain degree, in favour of the theory; but still it is only a supposition. Andral and Louis have not found in their statistics of phthisis that fistula in ano is a common accident; the contrary opinion, in spite of numerical statements, prevails, however, and is supported by the observation of many. We have heard these abscesses explained by the continual paroxysms of coughing, and we were inclined to adopt this view, when accident led us to discover what we consider to be the most frequent cause of fistular abscess of the anus in consumption. In a consultation on a singular case of disease of the kidneys and bladder, one of the physicians, Dr. Ricord, diagnosed the presence of tubercles in the prostate gland. Another surgeon, who was also present, M. Amussat, stated that he considered the tubercular degeneration of the prostate gland as excessively rare, and for his part had never seen a single instance of it. M. Ricord, to whose wards we were then attached as *internes*, mentioned the circumstance to us, and expressed his surprise at M. Amussat's assertion. We were thus led to examine the prostate gland in a large number of cases of phthisis, and in many we found tubercular deposits, easily to be recognised on examination per anm. In general, the prostate was only diseased on one side, and the vas deferens often participated in the alteration. It is to this that we attribute the formation of anal and periurethral fistula in cases of consumption, and we consider that the embarrassment of the abdominal circulation mentioned by the contributor of the *Gazette des Hôpitaux* can only have a secondary influence in occasioning the development of abscesses.

SUICIDE IN FRANCE.—From the documents published by the Minister of Justice, it appears that during the year 1845, 3084 suicides occurred in France. In 1813, 3020, and in 1844, 2975 took place. These 3084 suicides were committed by 2317 men (76 per cent.) and 737 women (24 per cent.). 16 men and 4 women were under 16 years of age; 137 from 16 to 21 years; 176 from 21 to 30; 1215 from 30 to 50; 959 from 50 to 70; 217 from 70 to 80; and 50 above 80. During the three months of summer, 922 were observed; spring, 861; autumn, 756; winter, 545. 1110 were found hanged. 995 drowned, 432 used firearms, and 213 charcoal.

D. M'CARTHY, D.M.P.

Statistics of Ligature of the External Iliac Artery.—Dr. Wm. Norris, of the Pennsylvania Hospital, United States, has given an elaborate table, from the various works of surgery and other sources, in which operations on the iliac arteries have been recorded. Of 118 cases of ligature of the external iliac, included in the table, 85 recovered, 33 died, while three of the patients who recovered underwent amputation for gangrene of the limb. Of 113 cases in which the sex is noticed, 107 were males and 6 females. Of the 6 females, 5 laboured under aneurism, and 1 had secondary hemorrhage. Of 79 cases, in which the affected side is noticed, 44 were on the right and 35 on the left side. Of 99 cases, in which the age is noticed, 4 were under 20 years old; 23 were between 20 and 30; 32 between 30 and 40; 25 between 40 and 50; 11 between 50 and 60; 3 between 60 and 70; and 1 was above 70. Of the 118 cases included in the table, 97 were for the cure of aneurisms; 18 were on account of wounds or secondary hemorrhages; and 3 for the cure of varicose aneurisms. In 4 of the 97 cases of aneurisms that disease existed simultaneously in both the ham and the front of the thigh; and in 3 of these the operation cured both tumours. Of 78 cases, in which the period of the separation of the ligature is noticed, in 44 the ligature came away before the twentieth day; in 24 between the twentieth and thirtieth;

in 7 between the thirtieth and fortieth; in 3 beyond the fortieth day. The earliest period at which the ligature came away was the tenth day, and the latest was the sixty-second day. In 9 cases pulsation returned in the sac after the application of the ligature. In 14 cases hemorrhage occurred: of these 7 died, and 7 were cured. In 10 cases suppuration of the sac took place without any fatal consequence. Gangrene of the limb occurred in 16 out of the 118 cases, 3 of which were cured after amputation, and 13 died. Of the 118 cases, 33 died as before stated, viz., 6 from hemorrhage; 3 from sloughing of the sac; 13 from mortification of the limb; 1 from the bursting of an aneurism of the aorta at its bifurcation, ten weeks and six days after the operation; 2 from prostration, respectively on the third and fifth days; 2 from peritonitis; 2 of tetanus; 1 on the eleventh day, from some affection of the chest, probably disease of the heart; 1 on the second day, of delirium tremens; 1 of diffuse inflammation; and in 1 the cause is not noted. In two instances the peritoneum was wounded in the operation, but both patients recovered. In one the sac was accidentally wounded after the ligature was applied—the case above referred to, in which the patient was cut off by delirium tremens. In one the *vena circumflexa* was a source of much embarrassment to the operator.

Nature of Caries of the Teeth.—Mr. Hassall, in his "Microscopic Anatomy," says that various opinions have been entertained in reference to the nature of the peculiar decay denominated caries, to which the teeth are liable. Some have supposed that it is a vital process resulting from inflammation. The fact that dead teeth, that is, teeth which have been removed from the jaw and are again employed as artificial teeth, undergo a similar decay to that which affects the living teeth, proves that it is not essentially a vital action, although it cannot be questioned but that the condition of vitality and the state of development of the teeth must exert a powerful influence over the progress of the decay. Other observers regard the decay of the teeth as a purely chemical phenomenon, the earthy matter of the teeth being removed by the action of free acid in the saliva: this view of its nature certainly explains many of the circumstances connected with dental caries, and is supported by the fact already cited, viz., that dead teeth are susceptible of the change. Mr. Hassall has long entertained the idea that the real and proximate cause of the decay of the teeth was to be found in the presence of some parasitical production, and that the condition of vitality of the teeth and of the states of the saliva were to be considered merely as predisposing causes to the affection. This idea acquires some confirmation from an examination of the carious matter of a tooth: in it vast quantities of minute threads or filaments, possibly those of a fungus, are invariably to be discerned, as well as numberless dark granules and irregular masses bearing in some cases the aspect of true cells. The question may be asked, are these threads, granules, and cell-like masses anything more than the decomposing elements of the dentine, in which tissue it is that the chief ravages of the decay occur? The answer is, possibly not; but the surprising number of these filaments and the testimony of Mr. Tomes are opposed to the idea that they are the remains of the tubes of the dentine.

Nerves of Bone.—Nerves have not hitherto been satisfactorily traced into bones; nevertheless, the great pain experienced in diseased conditions of them proves incontestably the existence of nervous fibrillæ.

Paraplegia from Suppression of the Perspiration of the Feet.—Dr. Romberg cites the case of a man, aged forty-six, who had been troubled from his youth with profuse perspiration of the feet, and had suffered for two years past from frequent pains in the limbs, which were worse towards night, evidently of a rheumatic character, and had followed his getting cold and wet in the feet. The perspirations at last were suddenly sup-

pressed, and immediately after the patient experienced a feeling of weakness and loss of sensibility in the lower extremities. At first these phenomena were confined to the leg, but extended subsequently to the thigh and lower abdomen, and were accompanied by enuresis and constipation. He was able to move about on crutches, dragging the lower half of his body after him; but when seated, he could move his legs in any direction. Perspiration was limited to the upper half of his body, ending just below the umbilicus. The lower half was dry and desquamated continually. Sexual power was lost. The most careful exploration of the spinal column could discover no lesion. It was then conceived, that the suppression of the habitual perspiration from the feet at least indicated the *therapeia* in the case, and the foot-bath was prescribed, with half an ounce of nitromuriatic acid, thrice a week. In a fortnight the gait became sturdier, the patient was able to stand; the feet, hitherto cold and dry, became warm and moist. From gr. $\frac{1}{2}$ to gr. $\frac{3}{4}$ of the spirituous extract of nuxvomica was then administered, and in fourteen days the urinary bladder recovered its tone, and sensation returned to the lower extremities. After a few months perseverance in the treatment, the patient recovered perfectly, except a slight tottering in his gait. Another case somewhat similar occurred in a drunkard. Here the bladder and rectum were not paralyzed, nor was sensation lost, and the patient could move his legs when seated. It was found, on inquiry, that a profuse habitual perspiration from the feet disappeared immediately previously to the accession of the paralysis. Footbaths thrice a week, medicated with caustic potash instead of acid, and continued for a month, effected a cure without the use of any other remedies.

A New Form of Atrophy of the Face.—A woman, aged twenty-eight, had, at the age of thirteen, an attack of tertian ague. Three years afterwards she made a journey on foot through heavy rain, and very soon afterwards was attacked by what was probably scarlet fever. The mucous membrane of the pharynx was inflamed, the voice was hoarse, deglutition was painful, the uvula enlarged, and an abscess formed in the left tonsil. Externally the cervical glands were swollen. The general health was soon re-established, but it was found that the right side of the face appeared full, plump, and blooming, as it should be in a female of twenty, while the left was shrivelled and wrinkled like that of an old woman. The median line of the face constituted a sharp and distinct boundary between youth on the one side of the face and age on the other. On the wrinkled side the hair was scanty, and the forehead less convex; but, from the want of muscle and fat, the superciliary arch on that side was more strongly marked than on the right. Further, the eyebrow was nearly all gone, the eyelashes scanty, the caruncula small and pale, the eyelids large and thin, as compared with the right. The left side of the nose presented a curiously-atrophied appearance, as also the left side of the mouth and chin; and the morbid change could be traced down the same side of the neck to about the middle. The atrophy also implicated the left tonsil, left side of the uvula, &c. There was no loss of motion or sensation on the left side, and the secretion of tears, saliva, and perspiration, was not at all affected or interrupted. The only difference was, that the pulsation of the left carotid was weaker than that of the right, and was accompanied by a dull bruit not perceptible in the latter. Dr. Romberg, who relates the case, mentions others also, selected from the writings of other medical men.

Condition of the Kidneys in Diabetes Mellitus.—Dr. Romberg, in his work, noticed in "The British and Foreign Medical Review," mentions one case which came under his treatment. The urine was analyzed by Simon, and found to contain two ounces and three drachms of sugar to each quart. Iodide of iron, with a purely animal diet, was the treatment adopted, and at first with apparent benefit. Ultimately, how-

ever, the case terminated fatally. On an examination of the body, both pleura were found to contain serum; the upper lobe of both lungs contained crude tubercles, and in that of the right there was a circumscribed cavity of the size of a hen's egg. The lower was very voluminous and congested; the spleen wasted, flaccid, and internally of a brown colour, with soft macerated portions. Both kidneys were hypertrophied, firm, congested; the uterus normal; the bladder dilated, and its coats thickened. On more minute investigation by Dr. Remak, the cortical substance of the kidneys was found hypertrophied in consequence of thickening of the tubuli uriniferi, and especially congestion of the Malpighian glands, which were thus rendered visible to the naked eye. The tubuli had an opaque appearance, dependent on a deposit in the outer coat of fat-like granules. Free fat in the form of large globules was also strewn over the inner surface of the tubuli, and on the mucous lining of the pelvis of the kidney. The cellular tissue connecting the tubuli and Malpighian glands was indurated. No trace of sugar could be detected. It is very justly argued that the changes in the kidneys and bladder were secondary, caused by the stimulus of the saccharine urine.

Iodide of Iron in Albuminuria.—In the case of a drunkard, forty-five years of age, with febrile symptoms, headache, vertigo, &c., and oedema of the legs to the knee, and of the upper parts of the neck, the syrup of the iodide of iron was given with success, gradually from one-third of a grain of the salt to a grain.

Treatment of the Sequela of Scarlatina.—In simple anasarca uncomplicated with fever, the antiphlogistic diuretics, and particularly bitartrate of potass, were administered by Dr. Romberg. If there were febrile symptoms, and especially those of bronchitis, a small general bleeding was ordered, with infusion of digitalis, and the bitartrate of potass. In those cases in which thoracic effusion took place, this method was actively followed, conjoined with theunction of sublimate ointment, which was considered of great value. A drachm of sublimate is to be mixed with an ounce of lard, and the size of a hazelnut, or of half a tea-spoonful, is to be rubbed on a circumscribed spot on the chest about the size of a crownpiece, every hour until the skin becomes red. Shortly bullæ, like those of pemphigus, will appear, and when these have dried up, a new spot is to be selected, and treated in a similar manner.

Acute Rheumatism.—In the treatment of recent cases, general bleeding was first practised by Dr. Romberg; the painful limbs enveloped in wadding or tow to keep them at an equable temperature, and from seven to ten minims of the tincture of colchicum seeds given every two hours, combined with two scruples of sulphate of magnesia. In mild cases, this mixture was sufficient without venesection. The remedy found to be most efficient in shortening the duration of an acute attack, or in very obstinate chronic cases, especially those in which one joint was affected, was the bichloride of mercury. To adults, it was administered twice or thrice a day, in doses varying from one-sixth to one-third of a grain; to children, the doses varied from one-twelfth to one-eighth. Counter-irritants were applied in conjunction with the remedy. Rheumatic periostitis was a frequent disease, and was best treated with iodide of potassium.

Gangrene of the Mouth in Children.—This disease occurred in the Berlin Policlinic, under the two forms of stomacece and noma. It began in the alveolar periosteum, then the gums were affected, and lastly the teeth dropped out. Soma commenced in the cheeks, with an ashy grey speck that gave little annoyance, and was at first overlooked. This first began with swelling, hardness, and a peculiar fatty appearance, and then a dark gangrenous spot appeared, the preliminary to perforation of the cheek. The disease would then proceed with the most frightful ravages on the face, and not sparing

even the bones. Sometimes gangrene would attack other parts, as, for example, the labia pudendi of female children. It was, as usually, complicated with gastric disturbance and profuse diarrhoea, but seldom with typhus fever. It usually attacked cachectic children recovering from an infantile exanthematous fever, as measles, or scarlet fever. In the treatment an emetic was first given, if the patient was not too feeble, but generally a stimulating diet with cinchona was prescribed, and locally the application of sulphate of copper, five grains to half an ounce of honey of roses; or sulphate of zinc, ten grains to half an ounce; or the hydrochloric acid combined with honey, as an application, or diluted and used as a gargle.

Scirrhus of the Oesophagus.—The leading symptoms observed in two cases were, violent pains in the throat, vomiting immediately after and even during eating, acidity, and rapid marasmus. In the one case, the scirrhus was situated just above the cardia; in the other, there had been no pain felt for some months previously to death, but a most tormenting cough supervened in its stead, accompanied by the expectoration of a dark offensive matter. On a post-mortem investigation, the upper third of the thoracic portion of the oesophagus was found affected with scirrhus. There was a fistulous opening from the diseased part of the upper lobe of the right lung, to which, and also to the vertebral column, it was strongly adherent. The fistulous opening ended in a cavity in the lung about the size of a walnut, containing a carcinomatous ichor, and the whole lung seemed infiltrated. Contrary to expectation, a second scirrhous degeneration was found in the cardia, which was united to a tumour the size of a walnut, situate on the under surface of the small lobe of the liver. There was also a small tumour of stony hardness on the pancreas. This case is interesting, as proving that in scirrhus of the oesophagus other parts of the body may be implicated, contrary to the opinion of Rokitsanski.

Psoriasis Intractata.—Dr. Romberg found the aqua picis liquidæ to effect a cure when all other means failed. The aqua was prepared by pouring a quart of cold water over a pound of pitch, and leaving it to stand for twenty-four hours in a cool place; and a beer-glass of the water, filtered through paper, is to be taken every morning fasting, and the parts affected to be bathed with it twice or three times a day. Its use may be continued for months, the only apparent effects resulting being slight diuresis. Six cases are related in proof of the great efficacy of this remedy.

Chronic Eczema.—A very remarkable case was treated at the Berlin Dispensary, the patient being a highly hysterical female. The attacks recurred at intervals during three years. The last-mentioned was in January, 1840, and commenced with febrile symptoms, and a sensation as if hot water was being poured over the legs. In four-and-twenty hours the burning sensation extended to the surface of the body; on the next day, the epigastrium was covered with red spots, and in twelve hours afterwards bullæ appeared on the chest, generally of an oval form, and varying in size from that of a pea to a hen's egg, and even larger. One bulla formed by the union of several minor ones contained at least four ounces of fluid. The bullæ were developed from day to day on the body, on the face, within the mouth, and even in the vagina, old bullæ drying up, and fresh ones appearing. On the seventh day from the first eruption, when it was thought the disease had ceased, suddenly a new crop broke out on the face. On the tenth day these began to dry up, but, suddenly again, on the fourteenth day another eruption took place, but was principally confined to the mouth. When desquamation occurred, the hair and eyebrows fell off. Tar-water appeared to be the remedy that gave the patient most relief.

Influence of the Weather on Health.—Dr. Caspar, professor in the University of Berlin, in his essay on this subject, gives the following practical conclusions:—In Berlin, while the month of

January is the least, December is the most, favourable to health. The greatest number of deaths occur in spring, and the smallest number in summer. Extremes of temperature are dangerous to life. A high barometrical pressure tends to increase, while a low pressure tends to decrease, the rate of mortality. The influence of atmospheric pressure on human life varies in different seasons. No condition of the air is so dangerous to life as dry cold. On the contrary, humid cold has the greatest tendency to support life. Of all seasons of the year, the winter gives rise to the greatest number of cases of inflammatory diseases, while the spring is most fatal to them, especially to cases of pneumonia. Cold winters, warm springs, summers, and autumns, increase the danger and fatality attendant on inflammation attacking the brain and respiratory organs, and vice versa. The maximum mortality from phthisis occurs in spring, and after this season in winter. The minimum mortality in autumn and winter. Variations in the state of the atmosphere appear to exert but little influence upon the relative number of deaths from phthisis. Nervous fever is most frequent and fatal in autumn—least frequent and fatal in spring. The influence of weather and season on health varies with the different periods of life. This influence is most marked in the ages of infancy and puberty, but it is least marked in the first septennial period of existence. From the twentieth year upwards, the winter is the most dangerous, and the summer the most favourable, season to life and health; and the older the individual the more striking is this difference.

Influence of the Periods of the Day upon Births and Deaths.—Dr. Caspar has arrived at the following conclusions:—The greatest number of births occur between nine o'clock in the evening and six in the morning, while the smallest number occur between nine o'clock in the morning and six in the evening. The pains of labour commence most frequently between twelve o'clock at night and three in the morning; least frequently from six to nine in the morning. The influence of light is more marked with respect to the commencement of labour-pains than with respect to complete delivery. Amongst those births in which the pains commenced by day, the greater number were male children, and vice versa. On an average, the delivery was more protracted when the pains commenced by day than by night. The preponderance of nocturnal over diurnal births is more striking in respect to children born dead, than in respect to those born living. The maximum mortality occurs in the hours before noon, and the minimum mortality in the hours before midnight. Individually regarded, the ratio of deaths from inflammations, phthisis, and pulmonary hemorrhage, is greater in the afternoon; from fevers and exanthemata, just before midnight; from cerebral apoplexy, during the day; and from diseases of the nervous system in general, in the hours which immediately follow midnight.

Cyst in the Uterus of a Child three months old.—Dr. T. Lee exhibited to the Edinburgh Obstetrical Society the uterus and ovaries of a child that had died of an acute disease after a few hours' illness, and had previously exhibited no symptoms which had indicated any derangement of the genito-urinary organs. It was during the examination of the body after death that a vascular protuberance was discovered in one of the ovaries, similar to that which is observed when a corpus luteum is present. A section of this ovary disclosed a cyst, corresponding to the bulge upon its surface, having a dense fibrous capsule, thinly coated with a yellow curdy matter, and containing serous fluid. Both the ovary and Fallopian tube of this side were much larger than those of the other side. When the vagina and uterus were slit open, the lips of the os uteri appeared somewhat thicker and softer, and more pink in colour, than usual; and a round cyst, about the size of a small pea, and of a leaden hue, was found on the womb, closely and organically attached to it, just below the opening of the larger Fallopian tube, by a fibrous

base, the diameter of which was fully half of that of the cyst itself. This cyst, which was filled with fluid blood, was also composed of dense fibrous tissue, and became quite white, like the texture of the uterus, when the blood contained in it was washed away.

Preservation against Syphilis.—M. Debrasse states that he has discovered a method of preservation against the attacks of syphilis; that any part plunged for five minutes in the prophylactic liquid may be exposed with impunity to the contact of mucous membrane impregnated with the syphilitic virus. The liquid is said to be an astringent preparation; and the Government of Spain has referred the matter to the decision of the Academy of Medicine and Surgery of New Castile.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein Carfax, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

M. T. N. informs us "that he has been studying the primary cause of respiration and circulation, in hope of discovering the origin of the power which gives motion to the lungs and heart. The result is, I am able to advance a theory which I think will bear the test of physiological scrutiny." The "theory" is, that "vitality, or the primary cause of action in the lungs and heart, is derived from two fluids, or spirits, which contain opposing faculties. That is, one has the power of contracting the fibres through which it is diffused, and the other has the power of repelling them. The first, or contractive spirit, is generated in the brain, and conveyed to the heart, lungs, and intercostal muscles, through the eighth pair and sympathetic nerves. The second, or repulsive spirit, is generated in the liver, lacteal, mesenteric, and conglobate glands. It exists also in the carbonic acid which is given off in respiration, and in the oxygen of the atmosphere. This spirit is conveyed to the heart and lungs through the veins." Our correspondent has very liberally offered to dispose of the details of the "theory" if we should think them interesting to the readers of the Medical Times.

Chirurgus wishes to be informed where the bougies used by Mr. Briggs may be purchased, a review of whose work appeared in the Medical Times a short time ago.

A Union Surgeon.—The Halifax meeting has been followed by one at Matlock, a notice of which appeared in our columns last week. Our correspondent suggests that similar meetings should be held throughout the country; with which opinion we perfectly coincide.

M. S.—The assurance-office may be trusted.

Senex.—The preparation is a "patent medicine," professing to cure all diseases, merely to put money in the quack proprietor's pocket.

One who Signed the Irish Medical Protest.—The newspaper was duly received; the blustering of the state journals, we are quite aware, will not deter the Irish members of the medical profession from advocating their right to a fair remuneration for their services.

R. N., Gosport.—The subject will not be lost sight of; we continue to receive numerous communications, portraying in vivid colours the miseries of navy assistant-surgeons, and condemning the supineness of the Government.

Galen asks "if the members of the College of Surgeons possess any peculiar privileges?" We do not know of any. An unqualified person may recover for surgical attendance, as for work and labour done. The membership of the College, how-

from certain facts therein stated we must, for the present at least, abstain from publishing it.

Mr. E. Manvers.—The paper lies at our office and may be had on application.

A Medical Student, Edinburgh.—There is no professor of military surgery that we know of in any of the London medical schools.

Leotor.—Pericarditis, as a disease accompanying acute rheumatism, was known to the profession long before auscultation was practised.

An Inquirer.—The report is correct; the parties had no shorthand writer present, as they pretend, who published another statement.

A Constant Reader, Colchester, wishes us to caution the profession against an impostor, who is going about the country representing himself as a surgeon in distress. This is a trick, we are sorry to say, which is often practised, and with too much success.

A Candidate for the Diploma.—We are not in the habit of recommending "grinders;" practical knowledge is the best preparation for an examination.

A Medical Traveller.—In order to obtain the degree of M.D. from the University mentioned, the candidate must undergo five examinations and defend a thesis.

Amicus.—Our correspondent asks too great a favour. We cannot give the name of a person forwarding information to one who conceals his own; nor do we ever betray the confidence reposed in us.

A Retired Surgeon.—The facts stated are very important, and we should be glad of further information.

Mr. T. Coates.—There is no law prohibiting any class of persons from commencing business as chemists and druggists. The Pharmaceutical Society has no power to compel certain persons to possess their certificate.

A Young Surgeon.—"Chelius's System of Surgery" is now complete, and will suit our correspondent's views.

A Country General Practitioner.—Mr. Guthrie's Lectures on the Treatment of Wounded Arteries, lately published in the Medical Times, will give all the information required.

Veritas.—We have repeatedly given our opinion respecting the diplomas obtained by purchase. The trade, we hope, is now annihilated, Glissen having resolved that in future it will only grant the degree of M.D. to those who submit to an examination.

M.D.—The case has not been overlooked. We shall attend to it when we procure all the details.

Discipulus.—The Medical Times Almanac contains all the information our correspondent requires.

Mr. E. Williams.—The matter will be better understood when the whole of the papers are published.

G. L. G.—The manuscript has been unfortunately mislaid.

A Correspondent warns us against a practice advertised to be sold at Liverpool. He asserts that it is got up by a most arrant quack.

Civis.—We are aware that the graveyard nuisance is not abated. We have no doubt, however, that the time is not distant when the public will be sufficiently roused to insist that all interments shall take place at a distance from densely populated localities.

Dr. Wane, Putney, has requested us to insert the following reply to a correspondent, which we do with much pleasure:—"Extract from 'The Provincial Medical Directory':—'Wane, D., Putney, Surrey; General Practitioner, M.D., Edinburgh, 1839; M.R.C.S., Edinburgh, 1837; for three years resident physician and house-surgeon in the Royal Infirmary, Edinburgh. By a mistake, directed too late to be remedied, the name appeared on the unqualified list of the London Directory.'"

Medicus.—1. Not as an apothecary, but the debt can be recovered as for work and labour done. 2. Yes. 3. The law is imperative in granting fair remuneration "for work and labour done." 4. We do not.

Mr. Farmer's reply to Dr. Ross Cormack will be inserted, if possible, in our next number.

Letters and communications have also been received from M. T. N.; Chirurus; A Union Surgeon; M. S.; Senex; One who Signed the Irish Medical Protest; R.N.; Gosport; Galen; Dr. Robertson;

Mr. E. Manvers; A Medical Student, Edinburgh; Leotor; An Inquirer; A Constant Reader, Colchester; A Candidate for the Diploma; A Medical Traveller; Amicus; A Retired Surgeon; Mr. T. Coates; A Young Surgeon; A Country General Practitioner; Veritas; M.D.; Discipulus; Mr. E. Williams; G. L. G.; A Correspondent; Civis; Dr. Wane, Putney; Medicus; Mr. Farmer, Putney

THE MEDICAL TIMES

SATURDAY, AUGUST 14, 1847.

MEDICINE v. GOVERNMENT.

'Low remuneration!' "insulting niggardliness!" "parsimonious injustice!" "hard work ill pay!"—these are the "cries of London," and of the provinces too, as far as medical men inhabit them. Thirty thousand underpaid gentlemen spread over the British empire, and fighting a forlorn fight under one Hippocratic banner,—such is the spectacle we offer the country in this middle of the nineteenth century! We suffer under the plague of one wide-spread poverty; our groans are heard in every highway; thousands of our petitions darken the columns of the journals; and there is the sum of the picture! We lie as in some dark bottomless pit of despair, exhausting in useless, hopeless groans the energies that should bring extrication and light. We are "men of science," and "gentlemen," as we unceasingly do cry; and as if these precious privileges environed us like the Spanish king, with an etiquette of nullity or self-destruction, we live out our social torture in the screaming, sidgety, ineffective querulousness of hypochondriacal do-nothings!

Of course we are underpaid, ill used, kicked, cuffed, maltreated, in all the possible moods and tenses, in which social indifference or official ingenuity can do such things. But why? Are there two men in the profession that don't know the answer? It is because we work, and work very hard and very concurrently, for such treatment. We do our very best to merit it. The whole mass of us are toiling our utmost to uphold, extend, and perpetuate a system of low pay. Each does his best—pockets the small results—and then throws the onus on his neighbours! Every one of us is a rascal except the "gentleman" speaking to us, and he, "poor man," is a victim! "The system is shocking—dreadful—intolerable, especially to a man of fine 'gentlemanly feeling;' but, then, where there are such fellows as Jones and Smith, and that low-mannered fellow Tompkins, perking about one, ready to snap up everything, "what is a man to do?" And so the farce goes on from day to day, and the profession goes down from day to day. Everybody is a paragon to himself and a villain to his neighbours; and nobody seems conscious that we are all, all—nearly to the last man—tarred with the same brush.

Let us for a moment look our attacks of Government clearly in the face. Their official appointments are mean and niggardly. No doubt of it. Government deserves rebuke, and more than that—correction—for the unstatesmanlike parsimony. But if they give, we accept. The giver is surely not better than the thief. But mark how we receive! What compensation, what zeal, what anxiety, for the "disgraceful appointment!" We have in London some fifty

medical appointments for the metropolitan police army. There are always many men on each of these: they are spread over a widely-extending district: hundreds and thousands of painful and troublesome visits are given in the year, and what does each "staff-surgeon" get for his pains? Why—and we state it on irrefragable evidence—not so much as pays for his medicines! His drugs—his mere drugs to the police—are not fully paid for! Yet, if there be a vacancy, there are at least forty applicants, each with powerful influence and pressing claims, and the fortunate man who succeeds to the loss dubs himself "Surgeon to the Police" as if it were some great indication of good fortune or ability, and wears out his after-life in drugging his police patients with under-priced medicaments, and his reading—"club" journal with high-toned dissertations on professional standing!

What say we, then, to the low-paid union officer, and the non-paid police doctor—when they murmur, as they often do, their discontent in our editorial ear? This: "You are taken at your own price: why, then, complain? You fix your own price on your services by giving them: how, then, expect to have them higher rated? You, and men like you, alone support the system you condemn. You are as much the authors as the victims of the ill-doing. For the most paltry of advantages you have run to the "unclean thing," and while you adhere to it there is professional defilement. Unite—understand each other—combine with the rest of the profession: by your present activity make up for your past wrong: let there be a general resignation—and we shall soon have a general reformation." Here is the voice of justice as of policy: it is attainable, as every other good, by effort, by great effort, possibly; why, then, is something not done? We will say why. Because it is more pleasant to write a whine to the Medical Times than to make active common cause with a medical brother. Because we think worse of our neighbours than we even avow—which is saying much. Because, in fact, we are true to the character of our profession—which has less fellowship, less esprit des corps, and less public conjoint spirit than any other calling in the empire!

It is absurd in excess, though, by the way, the habit of our own, to abuse everybody and everything extra nos for our ill payments. We are better paid than we deserve to be, all things considered: and society estimates our services, if humbly, still far more highly than we do ourselves.

Where is there a man so fond of giving away as stock in trade—his visit and assistance—his scientific skill and advice as the doctor? He is never happy unless he is turning business to no advantage to himself. There is an actual contest who shall give advice gratis on the largest scale!

Observe that army surgeon, Mr. Screwloose: he is in full pay: he has his regiment to attend—and yet there, in one morning, he is writing prescriptions gratis for the over-fed flunkiey of a young Lord Dukeling who dined the day before at the mess; for the two Miss Tisicks, the major's maiden aunts; and so the good, benevolent doctor goes on, morning after morning, till the end of the chapter. On what principle does Mr. Screwloose thus undertake heavy, alien responsibilities for nothing—withdrawing from legitimate medical practice the very persons who should be made honestly to contribute to its support? It is unprofessional—

it is ungentlemanly—it is *unfair*: but then it is "*benevolent*," "*charitable*," and "*so good of him!*" Benevolent to aid a *peer*, by *chousing* son medical man of a fee! "*charitable*" to help a niggardly old woman to starve the doctor of her parish! "*so good of him!*" to *encourage* and to uphold a system which is the ruin and degradation of the profession!

It is that miserable public hoax, that passes under the name of "*charity*," which is, indeed, answerable for much of our system of low payments. We have been active—as a certain gentleman in a gale of wind—in teaching the world that our skill is a pure matter of unearthly generosity and philanthropy. It is a man's own fault if we cost him anything. We have been ingenious in devising modes by which the public shall be physicked, and we be nothing the better for it. There is Dr. Smallbeer, who founds a dispensary for the patients of other people! He was quite unhappy that the sick people of "*so large and populous a district*" as — should be actually *paying* (other people) for their medical attendance. Accordingly, getting a fair list of patrons and patronesses who pay each as *charity* one guinea for five guineas' worth of attendance, he opens an establishment which impoverishes his brother practitioners, and hurries himself into the *Gazette*! And this is *charity*—a charity which Lord Robert Grosvenor, through the "*height of the season*," disports over, like a May linnet, at the London Tavern, and which swells even into eloquence, during that genial time, the expansive bosom of the Duke of Cambridge! Oh, *Charity*! What iniquities are perpetrated in thy beauteous name! If by any accident the walls of our Free (ay, *very free*) Hospitals could open out and show our readers, as they may, the handwritings that "*charitable*" guilt has photographed on them, what lessons might we have for the public!—what improvements for the profession! We withhold, however, our hopes and expectations; they would be despair and gnashing of teeth to more than one professional philanthropist!

SAMSON AMONG THE PHILISTINES CRUELTY OF "THE LORDS."

פלשתים עליך

THE laconic epistle which the Irish medical remonstrants first received from Dublin Castle was indicative of what would follow from the Treasury gentlemen whose head-quarters are in Downing-street, London. "Coming events cast their shadows before;" and the Irish Government officials, knowing the minds of their masters, prepared the way for the decisive document which was intended as an everlasting *Actus* for refractory medical practitioners. Two brief letters the Government has thought sufficient to settle the remonstrants, in addition to the baiting which they should receive from those bulldogs of the press who are ready to worry and destroy anybody at the command of their official masters. The Castle has attacked the little band of medical patriots through the columns of certain newspapers, charging the gentlemen who signed the protest with a desire not so much of obtaining increased pay for dangerous professional services, as of injuring the Government by a religious and political agitation. Ireland, we know, is a "*potum nimborum*," and it was not to be expected that a movement like that which originated with some of the most illustrious members of the profession there, and which has for its object the attainment

of something approaching to a just remuneration for perilous duties, should arrive at the wished-for haven without encountering storms. No sooner had the medical patriots launched than the breeched Junos of Phoenix-park secretly implore the *Eoluses* of the press to let loose upon them such a hurricane of words as should accomplish their destruction.

"Incute vim ventis, submersaque obrue puppes;
Aut age diversos, de jice corpora ponto."

It was rather funny that this was to be accomplished by charging medical gentlemen with being political agitators and religious enthusiasts; in fact, with becoming conspirators against the Whig Government and the Protestant Church. Now, what this medical remonstrance has to do with "*church and state*," we cannot for the life of us imagine, as amongst the 1106 who signed the memorial are to be found men of every political sect, and of every religious denomination. It would have been utterly impossible to have gathered such men together in one band to effect the tremendous revolution which they are represented as contemplating. Medical men are proverbial for their noninterference with religion and politics: this does not arise, however, from the circumstance of their being powerless in the state: for their position, their education, and their services give them an influence which would tell greatly upon society if exerted, but on account of their being shut out from the holding of official stations under the Government. The neglect which they have experienced from the supreme Executive has produced a listlessness in political affairs which has operated greatly to their own disadvantage, and, now they have approached the Treasury doors requesting something like a fair remuneration for their services, they are repulsed with a haughtiness which shows themselves and their skill both lightly esteemed.

The insolence of officials has always been proverbial, and in the present instance it has manifested itself by calling the gentlemen who signed the remonstrance "*combinators* for a rise in wages, whining supplicants for a dole of public money," who exhibit none of the attributes of common sense, and whose statement of the most important facts is nothing better than vulgar "*botheration*."

To this tirade of the Government hirelings against the medical profession we append the last official document received from the Lords Commissioners of the Treasury, through the Lord Lieutenant: it is as follows:—

"Dublin Castle, July 26, 1847.

"Sir,—I am directed by the Lord Lieutenant to state that the memorial from physicians and surgeons, complaining of the rates of payment allowed under the temporary Fever Act, having been submitted to the Lords of the Treasury, their lordships are of opinion that the remuneration is as high as, under the circumstances of the case, they should be justified in granting.

"I have the honour to be, Sir,

"Your obedient servant,

"T. N. REDINGTON.

"To J. W. Cusack, Esq., M.D."

There is something about the conduct of the Government, as exhibited by its notes and through the medium of the press in its service which certainly reflects anything but credit upon its members. The Irish medical profession is just informed that its case is handed over to the Treasury Commissioners; and forthwith these gentlemen send back to the memorialists a declaration that the remuneration for their services "*is as high as, under the circumstances*

of the case, they should be justified in granting." Be it remembered that this proclamation has been addressed to men whose labours have shed a halo of glory over medical and surgical science, and who are revered by Christendom for the services they have rendered to the world. It is a high honour for Ireland to number amongst her children some of the most illustrious medical philosophers; and it is a deep disgrace to any set of men, however high in office, to deliberately insult them. The Board of Health, composed of medical men, have been cognizant of this, and they exhibit at the present time the power of office to put a gag in the mouths of upright individuals who ought to be forward in speaking loudly against any acts of oppression towards their brethren. Better far had they have given up all connection with the Government, than to have become parties to the degrading remuneration of five shillings a day to the members of their own profession for the jeopardizing of their lives in the very hotbeds of disease; better far would it have been for their honour, if not for their pockets, if they had declared their entire disapproval of the conduct of the lords, when their official notes were flung in the faces of the 1106 remonstrants. In dealing with these "*lords*" were as niggardly of their paper and of the time of their clerks as of the public cash; and no voice from the board is lifted up to rebuke the unjust parsimony. Present case and honours may now sufficiently compensate for the loss of that esteem and confidence which the medical officers of the Irish Government once experienced from their fellow-labourers in the same vineyard; but the deeds of public men are registered in the archives of their country; and no Government patronage can bribe posterity to admire a dereliction of public duty.

But let us look to the circumstances of the case, which, in the opinion of their lordships of the Treasury make *6s.* a day a fair remuneration for medical services. Did they consult the paper of Drs. Cusack and Stokes, lately published in the "*Dublin Quarterly*," before they issued their fiat? We trow not. These we have a statement of the mortality of medical practitioners, from fever, in Ireland. From this disease that ill-fated country is never free; epidemic after epidemic occurring, so that, in town and country, its ravages are frightful. In Dublin, the deaths from fever actually double the deaths from the same cause in London; and it is a singular fact, that when medical men are attacked the disease develops itself in them with far greater malignancy than in the patients whom they attend. It is generally of a low type, with eruptions of macule often coming out at a late period of the case; and, as we learn from Drs. Cusack and Stokes, "*the nervous symptoms, of all the phenomena of fever the most alarming, commonly exist to a great degree.*" As a natural result the mortality of medical men is astounding. The census of 1841 gives the proportion of deaths from fever, to the mortality from all causes as 1 in every 10·50, and 1 in 3·4 of the deaths of the total class of epidemic diseases; whereas the deaths from fever among the medical profession show a mortality of not less than 1 in 2·29.

Dangers in the field of battle are nothing to be compared to those which are encountered in attending upon the sick; four-and-twenty per cent. of the profession fall in the discharge of their duties, while in war, we learn from official documents, that amongst the officers the mortality is not more than ten and a quarter per cent.

Truly this is a melancholy picture to contemplate; but we have not yet seen its darkest colours. How many widows and orphans are left to bemoan their hapless condition! Cast upon the world, with but few resources, their days are embittered by poverty, and neglect, and the grave is looked upon as the only quiet resting-place from all their sorrows. These are the "circumstances of the case" that justify the Lords of the Treasury in adhering to the resolution of rewarding Irish medical practitioners with 5s. per day for their arduous and dangerous avocations.

How different is the conduct of the Government when churchmen are to be provided for! Only within a few weeks the First Lord of the Treasury proposed to create four new bishops, each with a salary of some five thousand a year; and what have they to do? The question we will not pretend to answer; but of this we are certain, that they have not to undergo a tithe of the labours and privations which medical practitioners experience, for whose remuneration the Government can only spare as many shillings per day. A man whose head is immersed in a wig, and his body in lawn and satin, may count upon an after-life of ease and affluence, and the church inspires her sons with the hope of attaining to such a high vocation; while the members of the medical profession, with the most brilliant talents, may labour night and day for the State, without its making any provision for them in declining life. Of a truth the profession, like the ancient Hebrew champion, has slumbered; and the lords of the Philistines have for a season, at least, triumphed by their stratagems. The victory, however, reflects no honour upon those who have obtained it, and the profession will eventually acquire sufficient strength to force even Cabinets to act justly towards it.

We trust that the spirit which the memorialists have displayed will be felt by every physician and surgeon throughout the United Kingdom, and we shall then have no further reason to complain that professional services are lightly esteemed by the members of the Government, or to insist that our brethren deserve the ill treatment by their own supineness.

INADEQUATE REMUNERATION OF POOR-LAW MEDICAL OFFICERS.

THE power of the press to rectify the evils with which society is afflicted is acknowledged to be great, and through its instrumentality some of the most beneficial reforms have been brought about. It has measured its strength with the oppressor, and has come off victorious; and it has prevented the perpetration of many acts which, had they been allowed to exercise their baneful influence, would have undoubtedly retarded the progress of civilization. It has proved itself the watchful guardian of popular rights, and tyrants have ever sought to curtail its influence or to annihilate its power. If we look to the medical profession, we shall find that its social advancement has been greatly promoted by this omnipotent engine, and that the position now occupied by the general practitioners of the empire, so advantageous for the ultimate attainment of just rights, must be mainly attributed to the press. Through its exertions political hypocrites have been unmasked, collegiate despots have been made to quail, and thick-headed poor-law guardians have been unable quietly to sack the maintenance of the sick upon parochial medical of-

ficers. Medical men themselves have, through its exertions, been aroused from an apathy which for years had so paralyzed their energies as to make them an easy prey to the numerous enemies who sought to use them as tools for their own aggrandizement. It has proved the palladium of our liberties—the *Ægis* which has shielded us in the day of peril.

We have been led to these remarks by contemplating the movements of the profession in different parts of the empire to resist acts of oppression, whether emanating from Government authorities or poor-law functionaries. We recorded last week, in the pages of our journal, a meeting of poor-law medical officers connected with the various unions of the midland counties, which was held at the Royal Hotel, Matlock, Bath, to take into consideration the subject of pauper medical relief. The facts which were then developed are as humiliating to the profession as they must be astonishing to the public. The latter are scarcely aware of the very inadequate remuneration which medical men receive for those important services they render to the sick poor; and, as parochial burdens are anything but light, there has been little concern manifested for any acts of injustice towards deserving medical officers, so that some saving may be effected in parochial expenditure. It is a false economy, however, that would lessen a present outlay of money which must ultimately require greater calls upon the public purse. This must be inevitably the case when medical officers are inadequately paid. Very few will be found who will ruin themselves to benefit others; nor is it required, for we are commanded to love our neighbours as ourselves, and not more.

From the statements made at the meeting referred to, we find that the scale of pay for the medical officers is such as must make them either unjust to themselves or to others. In some cases we are told that the remuneration is as low as 1s. 3d. per case; for which very liberal sum the medical attendants have to provide drugs, horse expenses, and a dispenser; the distance over which they have to travel, in numerous instances, being enormous. Here is a sacrifice required of time, strength, and money; and it is absurd to suppose that duties will be as efficiently performed under these circumstances as if they were paid for by liberal stipends. The "screws" have endeavoured to remove all blame from themselves by placing it upon the medical attendants. We are told in the fable that Jupiter has slung one bag on a man's back containing his own infirmities, and another on his chest, containing the infirmities of others. To reverse the order is to make a man turn his back upon himself, and is an insult which he will not fail to resent. Poor-law guardians are not prone to look behind them to discover their own faults, being too busily engaged in contemplating the supposed faults of others. Of the tempter and the tempted, the former has always been considered the greater sinner of the two; and so it is in the present instance. If the poor are neglected, the sin lies at the door of the parochial authorities: for it is not to be expected that medical men will give their labours for nothing.

After all, the evils of which the profession now complain, in reference to the pay its members receive for their attendance upon the poor, can only be removed by their own efforts. It is not enough for the press to advocate their cause, but they must take it in their own hands, and

firmly resolve to effect their own salvation. This is only to be accomplished by the general practitioners following the example which has been set by the medical men of the midland counties. Meetings must be held, unity preserved, and Government memorialized. Boards of guardians should be no longer permitted to ride roughshod over their medical servants; and this they will be prevented from doing by a firm resistance of their aggressions, and by keeping their conduct constantly before the public eye. Blunted in intellect, and parsimonious in disposition, as the greater part of them are, nothing but the force of public opinion or a sense of shame will compel them to perform acts of justice to others; and it is truly galling for educated men to be placed under the authority of such boobies.

We think that the suggestion made at the Matlock meeting is worthy of consideration, viz., that a Government medical inspector, acquainted with the value of general practice, should be appointed to fix the salaries upon a just and equitable footing, and correct the abuses which have crept into the system through a parsimonious policy. We would say to our medical brethren, that, if they would expect success, they must meet, resolve, and act. We shall then hear no more of those acts of oppression towards medical men which disgrace parishes, injure paupers, and degrade the profession.

THE PROVINCIAL ASSOCIATION.

THIS body met at Derby on the 4th and 5th inst. From sixty to seventy gentlemen were present at various portions of the proceedings. Dr. Heygate presided. The report spoke of 1858 members, of whom nearly 600 are nominal or non-paying members. The following is the financial statement:—

Balance brought forward ..	£113	7	7
Receipts	1304	1	8
Total	1417	9	3
Expenditure	1439	19	7½

Balance due to Treasurer .. £22 10 4½

In other words, the Association is twenty-two pounds in debt. On the questions of Medical Reform, Poor-law Medical Relief, and the Benevolent Fund, the council had no satisfactory information to offer. Something had been essayed about some of them, but nothing had been done for any. After the report several speeches were made, and a very laudable anxiety was shown to rest the future utility of the Association more on its scientific exertions than its political manifestations. Several medical and surgical contributions were successively received (some of which we shall feel it our duty to notice), and the sittings terminated by a public dinner, much to the satisfaction of all present.

INQUEST AT PUTNEY.

WE beg to correct a mistake which appeared in our leader of last week, in reference to this inquest. The stomach-pump, we understand from a correspondent, was not used.

NATIONAL INSTITUTE.

THE first annual general meeting of the National Institute was held on Wednesday evening last, at the Hanover-square Rooms. The proceedings were animated and harmonious, and the fullest confidence was expressed in the Council. The treasurer's report exhibited a balance in hand of £195 9s. 11d. He proposes in our next to give a full report of the proceedings, from which, on account of the lateness of the week, we are precluded in our present number.

MEDICAL TESTIMONY.

Two questions are raised by the late assize trials in Northumberland.

A medical gentleman of Newcastle, Dr. Glover, was examined as a witness. He had made a nice and laborious analysis, absorbing considerable time, and demanding the exercise of great skill. His testimony was of the first importance to the public. It is to the interest of the public that such witnesses should be adequately remunerated. Yet the law requires them with a miser's hand. Dr. Glover said as much to the Judge: he put it to his lordship whether he ought not to be more liberally rewarded for his services, and named a not immoderate sum as the fee to which he considered himself entitled. It is to the honour of Mr. Justice Wightman, but far from honourable to our laws, that he admitted the justice of the claim, and said he would have awarded even more than was asked, but he has not the power to add one farthing to the ordinary pittance.

The other matter to which we wish to draw attention is the false economy which rejects the services of medical men at coroners' inquests, and degrades those inquiries into idle farces. We have often said, but it cannot too often be repeated, that there are many inquests which it is absurd to hold, if no *post-mortem* examination be made. In such cases as those to which we refer, it is impossible to ascertain the cause of death, unless the body be opened by a medical man. Yet Mr. Coroner holds his court, and twelve men, in the absence of any conclusive evidence, pronounce an unhesitating verdict, which further and more searching inquiry not unfrequently shows to be false. In the case which suggests these observations, a man was committed to take his trial for manslaughter, and appeared before the Judge for that purpose; but the cause of death could not be shown, no *post-mortem* examination had been made, and the prisoner was dismissed from the bar, his lordship bestowing a very proper rebuke on the coroners who decline the aid of medical men, and the magistrates who begrudge them their fees. The admonition was much needed, and we trust that it may have due weight in the proper quarters.

FORGERY OF MR. ROLPH'S NAME.

SIR,—I am instructed by Mr. Rolph, of Paradise-row, Bethnal-green, surgeon, to apply to you with reference to a letter purporting to be written by him, and published in the *Medical Times* of Saturday last. My client never wrote nor authorized the publication of such letter; and as the same reflects upon his character, and likely to be, and in fact is, highly injurious to him, I have to request you to give up the name of the author of it, and publish this, his denial of having written or sent it, or authorized it to be done.

I remain, Sir,

Your obedient servant,

FREDERICK TRITTON.

Three-Crown square, Southwark, Aug. 11.

*** We need not say that we were the innocent, passive, agents of this very foolish and wicked imposture. The MS. is at the service of Mr. Tritton, with any aid we can offer to trace the author of the forgery.—ED.

ASSISTANT-SURGEONS OF THE ROYAL NAVY.

[To the Editor of the Medical Times.]

SIR,—Many thanks to you for your exposition of the abuses which assistant-surgeons experience in her Majesty's naval service, and for your advocacy of their rights to an altered position on board ship. Nothing can be more degrading to a man of talent, and a member of a learned profession, than the society he is compelled to herd with while an assistant-surgeon, and the consequent indignities he is exposed to. The gun-

room officers intuitively identify us with the class we are condemned to associate with, because the service makes the distinction, and they conceive their importance is being swelled by carrying it out. The exceptions to this are, I am happy to say, numerous, but the general rule holds good. The following remarks exemplify the cruel hardships which we have to endure. My first appointment was to an eighteen-gun sloop, where I, in common, with five others, shared a dark habitation which could just afford us sitting room. The furniture consisted of a well-hacked table, with lockers (narrow bins for keeping messtraps and drinkables in) around that served the purpose of chairs. On entering this blackhole, the measure of my disgust was complete, and my desire to separate myself from a service where everything was so repulsive was extreme; but, as I had incurred an expense of £150 in obtaining the necessary outfit, I felt I could not make the sacrifice, so I was necessitated to remain. To add to my miseries, I could find no companion amongst my associates. They were composed of a clerk, who did not possess two ideas beyond writing a letter on service, and an acquaintance with the Queen's regulations for the navy; a newly-created mate, swelling with the importance of being the senior member of the mess, and an executive officer; a master's assistant, who must have been dug out of some very obscure situation, for he exhibited the most complete ignorance of the every day usages of civilized society; and two naval cadets, just emancipated from school, whose continual occupation consisted in skylarking, *alias*, doing everything calculated to prevent your pursuing any occupation requiring quiet. Reading is quite out of the question. To add to the sum of my misery, I had to sleep in the same part of the ship as the men (in a hammock), the only distinction being that I slept farthest aft. I leave you, Mr. Editor, to draw your own deductions from the above statement. The remedy is palpable enough. Assistant-surgeons ought to have a cabin, and mess with the Lieutenants, &c., in the gunroom. Their education demands it. Is not their claim stronger than that of the naval instructor?

ONE WHO CANNOT FORGET THE PAST.
Dublin, July 24.

THE MEDICAL PROFESSION ON THE OCEAN!

[To the Editor of the Medical Times.]

SIR,—Having noticed an article in your valuable journal relative to the miserable condition of assistant-surgeons in her Majesty's navy, I beg leave to bring before the profession and public, through the same valuable channel, the equally unfortunate lot of surgeons serving on board emigrant ships. All ships carrying more than 100 passengers are (or soon will be) obliged to carry a professional man; be this, however, as it may, in these times, when typhus fever is raging violently in most large seaports, captains prefer doing so to risking their own valuable lives! Ships leave this port monthly for New York and all American ports with passengers. My remarks apply chiefly to these. They are American-built vessels, the owners being men of large property. About a week before sailing the agents advertise for surgeons. Many men wishing to settle in the United States apply, and this especially in the summer season, and on demanding terms are very generously informed that their services will be remunerated by a free passage to the port of destination. Many fools (for such they undoubtedly are) catch at the opportunity of saving the price of a cabin passage (never dreaming that he trouble they will have would not be a quarter recompensed by the berth), and engage, deriving others, perhaps, more competent of their bread; but, what is in my estimation worse than all, lowering the honourable profession of which they are members by offering their services for nothing! Should these gentlemen have a rough

passage, and any considerable sickness on board, my own experience tells me repentance will be their lot long before they have made half-passage, leaving wholly out of consideration their own unavoidable sea-sickness and the many unmentionable disagreeables of the hold of an emigrant merchantman. The purport of this paper is to bring before young surgeons, in a clear light, the absurdity of accepting such disagreeable and, I may safely say, dangerous berths at no remuneration, or even at a small remuneration!

Let all surgeons serving on board emigrant ships (and especially American ships, where the greatest meanness is practised) demand their six or eight pounds a month, and thereby raise themselves, at all events, to the rank of a second mate. Let all do so, and all will be well paid. But where men can be found to undertake such abominable situations *gratis*, such men will always keep more deserving brethren in poverty and in the background. Let all demand a liberal remuneration for their services, and when the law comes into force which will compel ships to carry surgeons, the owners (who are, as I said above, all rich men) will be obliged to treat them as gentlemen. At this present moment there are fifteen or twenty ships carrying surgeons to New York, who only receive their free passage, and who have to find themselves while in port. This is a subject which requires serious consideration, and which I am convinced can only be remedied by liberal-minded men. The professionals are, indeed, badly paid on shore; but nothing can equal the degradation they suffer on the sea. I speak from experience, having myself crossed the Atlantic in the capacity of surgeon. I have often applied for a similar berth, and, on stating my terms, have been told that they could get men for nothing. I know that some captains are in the habit of giving their ailing passengers bread pills, instead of carrying a professional man. Such meanness requires trampling under foot.

A WELL-WISHER TO HIS PROFESSION.
Liverpool, Aug., 1847.

VALUE OF THE APOTHECARIES' LICENSE.

[To the Editor of the Medical Times.]

SIR,—In your answers to correspondents of last Saturday you tell Mr. Oldfield that the "Apothecaries' Society would feel it an honour to rid the place of such mountebanks." When has this change come over the spirit of their dream? for, when any application is made to the Society for protection or assistance against quack and illegal practitioners, they send back a *printed letter*, ready cut and dried, signed by the clerk, that they can afford no protection or assistance, and if you want any you must prosecute at your own expense. Well might Mr. Ebsworth and others ask "if the Society was in existence?" for any credit or protection they are to their licentiates, they might as well be "down among the dead men." I have no hesitation in saying that the Company have acted false to their trust. Did the Legislature ever suppose, when they gave them a penal clause in their act, that they would abdicate that important privilege by calling on their licentiates to fulfil it, after they had pocketed their money?

May I ask, what was the meaning of that flourish of an advertisement that the Society published last winter in the *Medical Times*, setting forth that by the new interpretation of their act, &c., "any person so offending would be indicted for a misdemeanour, and that the Society were resolved rigorously to carry it into effect"?

Had the dread of the registration clause of Mr. Wakley's bill anything to do with it, think you? Many are of that opinion now. Even you, Sir, in your denunciation of that bill, asked "what benefit would it confer that the new reading of the Apothecaries' Act did not already possess, and was found to work well?" How has that pledge been since fulfilled?

Could not the National Institute form a fund for the protection of their associates? It would not be unworthy of them.

It may be all very fine to possess corporate privileges, &c. &c.; but I ask, what use would it be to confer the order of knighthood or any other title upon a *beggerman*, when he has not wherewithal to support it?

A case was a short time since privately submitted to you for your advice: it stated that a gentleman in a remote country village, who made for himself a practice sufficient to support his family in respectability, &c., and that, within the last twelve months, a fellow—a sort of half assistant, half porter, in a druggist's shop—had set up in opposition to him, as a general practitioner; and that his business and receipts were most seriously injured by this illegal intrusion. You replied "that the Apothecaries' Society would certainly prosecute him." Well, he applied to the Society, setting forth the case; he received the usual printed circular, intimating to him that he should prosecute at his own expense. I this morning received a letter from him in the greatest affliction, stating that his affairs got deranged, he could not meet his engagements, and that the landlord had put in a "distress" and seized upon his furniture, and where to turn to he did not know; and yet a more high-minded, honourable fellow never existed; driven out upon the world by this unprincipled scoundrel, and by the shameful indifference of that body from whom he should have received protection and assistance.

Would it not be as well to publicly intimate to all quacks, that they may kill and practise with perfect impunity: they will not be interfered with; and that all medical students who may now be stewing, grinding, &c., may save themselves the trouble and expense; as the Apothecaries' certificate is perfectly worthless.

I trust, Sir, to your impartiality to publish this plain unvarnished letter, and that others, and doubtless they are numerous, may be induced to do so likewise, until public opinion be brought to bear against the Society, and compel them either to do their duty or resign a trust for the fulfilment of which they have proved themselves perfectly incapable.

AN OLD SUBSCRIBER.

COLLEGE OF SURGEONS.

Copy of a Letter from the President of the College of Surgeons of England to the Secretary of State, written in March, 1846; and of the Answer of the Secretary of State to such Letter.

● Royal College of Surgeons of England, March 16, 1846.

SIR,—I have the honour to transmit to you a copy of resolutions passed by the Council of this College on the 11th inst., and confirmed on the 14th, relating to an application to her Majesty for a supplemental charter.

The Council will feel obliged if you will favour them, at as early a period as convenient to you, with your opinion on the propositions, in order that the draught of a charter may be prepared in conformity therewith, should they meet with your approbation. I am, &c.,

(Signed) SAMUEL COOPER, President.
The Right Hon. Sir J. Graham, Bart., &c. &c.

Copy of Resolutions of the Council of the Royal College of Surgeons of England, on the 11th of March, 1846.

That a petition be presented to her Majesty, praying for a short supplementary charter, enabling this Council, in the first instance, to arrange the two lists of members elected and appointed to the fellowship (under the authority of the charter) on the 11th of December, 1843, and the 26th of August, 1844; so as to place them in the order of seniority according to the dates of their respective diplomas as members. And further to give authority to this Council to admit, by ballot, from time to time, to the rank

of fellow, without examination, all members of the College of twenty years standing, on producing to this Council certificates from seven members of the College, three of whom, at least, shall be fellows, that, on their own personal knowledge, the members to whom the said certificates are granted, are men of strict moral integrity and of high professional acquirements as practical surgeons; and that this manner of admission to the fellowship be limited to those who were members of the College on the 14th of September, 1843, the date of the late charter.

That all who were members of the College on the 14th of September, 1843 (the date of the late charter); and who have been, or may be, admitted fellows, shall take precedence on the chronological list of fellows, according to the date of their diplomas as members.

That those members who shall be admitted to the fellowship without examination, in the manner directed in the proposed supplemental charter, shall pay the same fee as is required by the by-law (sect. 3, para. 4) to be paid by members when admitted to the fellowship upon examination.

(Signed) SAMUEL COOPER, President.

Whitehall, March 23, 1846.

SIR,—I have taken into consideration the resolution of the Council of the Royal College of Surgeons of England relating to an application to her Majesty for a supplemental charter.

When the great change was made in the constitution of the College, rendering the Council elective by the fellows, it became necessary to constitute forthwith a body of electors, in aid of the gradual process of the introduction of fellows after examination. It appeared to her Majesty's advisers that the privilege of selecting members for this purpose might properly be given to the Council, who were accordingly empowered at once to enrol as fellows a list of 300 members, who might appear to them most deserving of that distinction. And, to obviate the consequences of any accidental omissions from this first list, this power was continued for twelve months after the date of the charter, which time seemed long enough to allow of the detection and rectification of any such omissions.

The charter provides that, with the exception of those who should be so admitted within the year, no person should be admitted a fellow until he should have passed a special examination and complied with the other requisites of the charter.

I have heard with great satisfaction that the beneficial effects which were anticipated from holding forth to young men the honour of the fellowship, to be gained by superior attainments, are in a fair way of being realized; and that a great encouragement has been given to those who aim at a high standard of professional education.

It has of course not escaped the consideration of the Council that there is room for apprehension lest the consequences of acceding to their present application should have a contrary tendency, and that the value of the fellowship may be proportionally impaired, as the number is increased of those who have been admitted to it, without giving open proofs of their superior qualifications.

I am not uninformed of the jealousies to which the distinction of classes among the members of the College has given rise, and I feel myself bound to suppose that the Council, having more ample means of information on the subject than I can command, have come to the conclusion that the probability of allaying these feelings by the alteration now suggested by them, is worth the risk of the inconvenience to which I have alluded.

Relying, therefore, as I have hitherto found myself fully warranted in doing, on the enlightened zeal of the Council to promote the best interests of the College, I shall not be indisposed to advise her Majesty to sanction the introduction among the fellows of those members contemplated by the resolution of the Council,

The other parts of the resolution refer to the future order of rank among the fellows.

If this were a mere question of ceremonial precedence, it would be of very secondary importance; but it assumes a very different aspect when viewed in connection with the manner of election into the Council.

It will not be forgotten by the Council that I from the first disapproved of the principle on which that mode of admission was formerly founded. In consequence of my representations, the Council agreed that it should be in some degree modified and rendered less objectionable in the recent charter, by affording a second opportunity for nominating a fellow for election to the Council, who had been once passed over; but the Council at that time were unwilling to abandon altogether the principle of nomination in the order of seniority, and I acquiesced in their final resolution, rather than be deprived of the advantage of their concurrence in the other important changes effected by that charter.

The inconvenience which I then anticipated will be greatly increased if I should advise her Majesty to sanction your proposal of ranking each fellow, upon his admission, according to the date of his membership, without making any change in the manner of election to the Council.

The consequences would be that, for the next seventeen years, none of the young fellows could calculate with any certainty on his chance of election to the Council, and the unlimited introduction of the certificated fellows, which will probably be viewed with jealousy by those who come in upon examination, will become a more palpable grievance, and will be more deeply resented. I understand that the settlement of this question is considered essential for producing the harmony which the Council hope to restore by the new measure; but, upon the mature consideration I can give to the subject, I cannot recommend any alteration of the order of precedence among the fellows, unless it be accompanied by a change in the manner of election into the Council.

I do not think it desirable that every fellow should be indiscriminately eligible to that honour; nor do I wish to prescribe the exact conditions of eligibility; but it would appear to me a reasonable proposition, that the members of the Council should be chosen exclusively from those who had been fellows for at least ten years, or fellows and members for at least twenty-five years. On this question I shall wish to learn the opinion of the Council, when they shall have reconsidered this matter, after being made aware that I look on an alteration of this kind as an indispensable preliminary to a new arrangement of the order of precedence among the fellows.

I have, &c.,

(Signed) J. R. G. GRAHAM.
The President of the Royal College of Surgeons of England, &c.

GOSSIP OF THE WEEK.

UNIVERSITY OF LONDON.

First Examination for the Degree of Bachelor of Medicine, 1847.

The following is a list of the candidates who have passed this examination:—

First Division.

Richard Dechamp Ball, University College; Thomas Snow Beck, University College; Cornelius Black, Edinburgh School of Medicine; Charles Crighton Bramwell, University College; Thomas Bridgwater, King's College; Soorjoo Coomar Chuckerbutty, University College; W. T. Garret, Woodford Clapp, University College; George Robert Cubitt, King's College; Samuel Weston Devenish, Guy's Hospital; Joseph Drew, Royal Manchester School of Medicine; Samuel Griffith, King's College; Frederick William Pearce Jago, London Hospital; John Cox Lynch, King's College; James Morris, University College; Hubert Shelly, Guy's Hospital; Josiah Willott, Guy's Hospital.

Second Division.

James Bailey, University College; Edward James Franklyn, University College; Thomas Green, Royal College of Surgeons in Ireland; George Renorden Kingdon, St. Bartholomew's Hospital; William McCrea, St. George's Hospital; Henry Parfitt, King's College; William Henry Octavius Sankey, St. Bartholomew's Hospital; Edmund Whitaker, Royal Manchester School of Medicine.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma of this college, were admitted members at the meeting of the Court of Examiners on Friday evening last, the 6th inst., viz.:—Messrs. A. Jubb, Malilax, Yorkshire; J. Ralph, Bethnal-green; W. Thompson, Addison-road North, Notting-hill; W. D. Wilkes, Salisbury; R. E. West, Camelford Cornwall; J. Ingman, Treddyn, Flintshire; J. Willan, Kirkby Lonsdale, Westmoreland; J. C. Nicholls, London; J. McCance Blizard, Belfast Ireland; D. De Lacy Ryan, Ennis, county of Clare; and J. F. Knipe, Stillorgan, near Dublin. —On the 9th inst., viz.:—H. J. W. Welch, W. A. Duncan, C. G. Brown, C. Thompson, G. Hother, R. C. Scott, D. W. Williams, T. F. Heslop, S. J. A. Salter, and W. W. Edwards.

APOTHECARIES' HALL.—Gentlemen admitted members August 5: George Winter Rhodes Jabez Harwood, Edward Nason, John Edward Ellenton, John Waddington Hubbard, Walter Dawley Eddowes, William Daniel Michell and Henry Axford Mantell.

WAR-OFFICE, July 20.—5th foot: Dudley Hamley, M.D., to be Assist.-Surg., vice Batley, who resigns. —29th Foot: Assist.-Surg. Ludovic Charles Stewart, from the 50th Foot, to be Assist.-Surg., vice Young, who exchanges. —50th Foot: Assist.-Surg. W. Baker Young, from the 29th Foot, to be Assist.-Surg., vice Stewart, who exchanges. —August 6.—4th Dragoon Guards: Surgeon Chilley Pine, from the 58th Foot, to be Surg., vice William Gardiner, who retires upon half-pay. —11th Light Dragoons: Assist.-Surgeon Robert Bridgeman Wigstrom, from the 59th Foot, to be Assist.-Surg., vice Thomson, promoted in the 58th Foot. —12th Foot: Assist.-Surg. Nesbitt Heffernan, M.B., from the 17th Foot, to be Assist.-Surg., vice Chambers, promoted in the 35th Foot. —35th Foot: Assist.-Surg. James Walker Chambers, M.D., from the 12th Foot, to be Surg., vice Lister, deceased. —57th Foot: Assist. Surg. Johnstone Thomson Richardson, from the 60th Foot, to be Surg., vice Hunter, promoted on the Staff. —58th Foot: Assist.-Surg. Arthur Saunders Thomson, M.D., from the 14th Light Dragoons, to be Surg., vice Pine, appointed to the 4th Dragoon Guards. —59th Foot: Thomas Connor O'Leary, gent., to be Assist.-Surg., vice Bridgeman Wigstrom, appointed to the 14th Light Dragoons. —Hospital Staff: Surg. Robert Hope Alston Hunter, from the 57th Foot, to be Staff-Surg., of the First Class.

GUY'S HOSPITAL.—The triennial prize of 300l., founded by the late Sir Astley Cooper, Bart., has just been awarded by the physician and surgeons of this institution, to Dr. Richard Halahan, for his essay on the "Uses and Structure of the Supravental Capsules." Dr. Halahan is the son of the late Professor Halahan, of the Royal College of Surgeons of Ireland.

BRIDWELL HOSPITAL.—Mr. Holmes Coote, the surgeon of the North London Ophthalmic Hospital, has just been elected assistant-surgeon to this institution, in the vacancy occasioned by the resignation of Mr. J. T. Crookes.

A SPOTTED CHILD.—A foundling child was brought to the New York Almshouses some time ago, a girl about sixteen months old. About one half of the body was of a fair complexion, and the remainder of a rich copper colour, and the dark spots were all covered with a long white hair. In the centre of its forehead was a round dark spot, and the same hue covered the breast and legs.

BRITISH MUSEUM.—On Monday week several

cases of Assyrian sculpture, from the ruins of the city of Nineveh, were deposited in the gallery of antiquities. They were originally intended for the French Government, but, from a misunderstanding that arose between the collector and the French authorities, they were offered to the trustees of the British Museum, who became the purchasers; they are considered the finest specimens yet discovered. The Xanthian collection of sculpture and architectural remains is now nearly complete, and will be open to the public in a few days.

INVISIBLE SPINE SUPPORTER.—We have lately had our attention drawn to a valuable instrument of this kind, devised by Mr. Eagland, of Coventry-street. The grand purposes of such means, namely, the withdrawing of pressure from the spine, and the gentle opposing of force to the curvature, seem admirably answered. Mr. Eagland invites the inspection of the profession.

It has appeared in the *Gazette Med. Belge* and other papers, that a dentist in Paris has been arrested for using violence to a young person etherized by him. The Society of Dentists at Paris beg to assure the public that the culprit has been practising without a diploma. Consequently the honour of the legal profession remains unimpeached.

We learn that a well-organized medical society has been founded at Athens, and that it cannot fail to contribute greatly to the progress of medical science. Dr. Dumanos Georgius, a physician of eminence, is the secretary of this society.

The number of prisoners increase every day in the gaols, both civil and military, at Gand, consequently the typhus fever is gaining ground. There are now twenty-five prisoners and two gaolers dangerously ill. Government should take some measure to avoid such an encumbrance. With every precaution, it is impossible for half a thousand persons to be heaped in a building only made to contain two hundred. We learn that the typhus fever continues to rage at Gand, in the lock-up house, so much that several prisoners have been sent to Saint Bernard and Vilvoorde; others were provisionally set at liberty.

HARVARD UNIVERSITY, BOSTON, U. S.—Dr. Warren having resigned the chair of anatomy and physiology, the corporation has appointed three new professors, two of whom are to be attached to the Massachusetts Medical College in Boston, and one to the University at Cambridge. The new incumbents are O. W. Holmes, M.D.; J. B. S. Jackson, M.D.; and J. Wyman, M.D.

AMERICAN NATIONAL MEDICAL CONVENTION.—The delegates assembled on the 5th of May last, at Philadelphia, Dr. Isaac Hayes in the chair. Among the resolutions reported by the committee was one recommending to the medical schools of the country to extend the lecture term to six months, and to demand of the medical student higher preliminary attainments. It appears the amount of literary knowledge required is at present very slender. The meeting appears to have been highly satisfactory to all the members assembled, and it is expected that beneficial influence will be exerted by the convention, although the progress of reform must necessarily be slow and, perhaps, tedious.

SHIP FEVER IN NEW YORK.—From the destitution of the emigrants who have recently arrived in New York, and the crowded state of the vessels in which they are brought, many are affected with ship fever. In several instances it has proved fatal, and is said to be contagious.

NAVAL APPOINTMENTS.—Surgeons: W. Folds, to be Surgeon of Devonport Dockyard; James Wilson, to the Royal Sovereign yacht, vice Folds; Dr. John Robertson, to the Caledonia, vice Wilson; Charles R. Kinnear, to be Superintendent of the Cadet, convict ship; Hugh T. Beveridge, to the Imaum. —Assistant-Surgeon James Henry, to the Antelope.

The managers of hospitals in Paris are about to organize a small agricultural colony for deranged children.

NAVAL PROMOTIONS.—Assistant-Surgeons: Dr. W. McKinlay (1838) and Dr. A. Graham (1838), to the rank of Surgeon.—Deputy Medical Inspector Dr. R. Armstrong, of the Royal Hospital, Plymouth, to the rank of Medical Inspector, and appointed to that establishment, vice Sir D. J. H. Dickson, M.D., retired.

NOVEL APPLICATION OF ETHER.—Several successful experiments have recently been made in France on the etherization of bees, so as to be able to take their honey whilst they are in a state of inaction, without the necessity of destroying their lives.

THE ASTLEY COOPER PRIZE.—The subject selected by the umpires for competition for this prize for the year 1850 is, "On the State of the Blood and of the Bloodvessels in Inflammation, ascertained by experiments, injections, and observations by the microscope." It will be recollected that this prize was founded by the late celebrated surgeon whose name it bears, and is of the value of £300.

The Legislature of the state of Connecticut have just decided the question as to who discovered that insensibility could be produced by the inhalation of ether. They proclaim, after long scrutiny and debate, that this discovery belongs to Dr. Horace Wells, of Hartford.

Great preparations are making at Haydar Pacha for the feast of the circumcision for the sons of the Sultan. Eight thousand children are to be circumcised with the two princes, who will each receive a complete suit of clothes and a sum of money. It is supposed the expense of this fête will exceed 60,000 bourses (about seven millions of francs). On Thursday, the treasurer, the steward of the Sultaness, Tahir Pacha, the chief physician of the kingdom, his Excellency Ishmael Effendi, and the chief eunuch of the Imperial Palace, were to repair to Haydar Pacha, to inspect the work, and to take down the necessary depositions.

We sincerely regret to announce the death of the eminent and amiable Dr. Andrew Combe, who died at Gorgie Mill, near Edinburgh, at twelve o'clock on the night of the 9th of August.

MORTALITY TABLE.

For the Week ending Saturday, August 7, 1847.

Causes of Death.	Total.	Average of 5 Summers.
ALL CAUSES.....	998	940
SPECIFIED CAUSES...	994	935
Zymotic (or Epidemic, Endemic, and Contagious) Diseases.....	311	26
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable Seat.....	99	103
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	140	157
Diseases of the Lungs, and of the other Organs of Respiration.....	185	226
Diseases of the Heart and Blood-vessels.....	26	25
Diseases of the Stomach, Liver, and other organs of Digestion.....	106	94
Diseases of the Kidneys, &c. Childbirth, Diseases of the Uterus, &c.....	9	8
Rheumatism, Diseases of the Bones, Joints, &c....	5	10
Diseases of the Skin, Cellular Tissue, &c.....	10	7
Old Age.....	8	2
Violence, Privation, Cold, and Intemperance.....	38	50

SUGGESTIONS

FOR A MORE SIMPLE ARRANGEMENT OF THE

MATERIA MEDICA,

BASED ON ITS PHARMACEUTICAL AND THERAPEUTICAL RELATIONS.

By GEORGE LEITH ROUPELL, M.D.

Cantab., F.R.S., Fellow of the Royal College of Physicians, Physician to St. Bartholomew's Hospital, Lecturer on *Materia Medica* at the College of St. Bartholomew's Hospital.

(Continued from p. 481.)

LECTURE VI.

The division of the alkaloids which I have next to consider is composed of such as are amorphous in form, not crystalline: these are aconitina, veratria, delphinia, and emetina.

11. Aconitina, one of the most powerful substances in nature, is so active that one fifteenth of a grain administered internally has occasioned the most alarming symptoms, which were not dissipated without much apprehension of loss of life; and a twelfth of a grain given to a bird destroyed it, we are told, with the "rapidity of lightning."

Aconitina has been introduced into the Pharmacopœia, and is made by precipitation of the alkaloid by ammonia from the solution of the sulphate, and then purifying it by animal charcoal.

Aconitina appears either in the form of a white amorphous substance, or in the shape of a transparent resin-like mass, having an acrid, bitter taste, benumbing the tongue, and causing a sensation of heat which lasts from ten to twelve hours. It is very little soluble in water, readily so in alcohol and ether. Its formula has not yet been agreed upon. Aconitina has only hitherto been employed in practice as an external application; and care must be taken even when this is done that there be no abrasion of the cuticle. Used in this way, aconitina, when pure, is a gigantic remedy, one hundredth of a grain creating a sensation in the part which will last a whole day. Aconite given internally, or applied topically, in the form of the dry leaf or the extract or tincture, produces various effects upon the system.

Applied locally, it allays pain and diminishes muscular power. Given internally, it acts upon the sentient and motor power as a direct sedative, producing at the same time a remarkable tingling in various parts of the body, especially the head, face, and extremities. It influences, moreover, the action of the heart, lessening the frequency of its beats, lowering its power, inducing a state allied, according to Dr. Fleming, to excessive exhaustion, and producing death by syncope, preceded by loss of sight, hearing, and speech. It is then a calmative, an anodyne, and an antispasmodic; and it has been recommended in cases of inordinate action of the pulse, in pneumonia, pleurisy, phrericitis, and rheumatism, both in the acute and chronic stage. In neuralgic affections, in spasmodic asthma,

and in painful malignant disease, benefit is said to be derived from it.

The preparations of aconite are the dried leaf, the extract, and the pure alkaloid. A tincture is in use, and this is a good form both for the external application and for internal exhibition.

12. Veratria is the active principle of the veratrum album and the sabadilla. This alkaloid is met with in commerce as a light brown powder; but doubts are entertained as to whether it has yet been ever obtained in a state of purity. It is insoluble in water, soluble in alcohol, its taste is acrid, and its local action is that of an intense irritant, producing active inflammation when applied to the mucous membranes, and if to that of the nose violent and dangerous sneezing. It acts also upon the nervous system, giving rise to stupor and convulsions.

Veratria has been applied externally in the endermic method, and has been found serviceable in neuralgia, disease of the heart, rheumatism, paralysis, and dropsy. It is employed externally, also, as a means of destroying the parasitical animals which infest the human body.

Internally the preparations of veratrum are recommended in gout and rheumatism, but for these it has been superseded by colchicum. Veratria differs chiefly from colchicia in its greater acidity, in its insolubility in water, and in not crystallizing. In their therapeutic effects these alkaloids are nearly identical. The preparations of veratrum have also been used in cutaneous affections; but they need not occupy me longer, except to mention that they are a wine, a decoction, and an ointment.

13. Delphinia is the active principle of the staphisagria. It appears in a pulverulent form, insoluble in water, soluble in alcohol and ether, and has an acrid, bitterish taste. Applied to the skin, it creates a sensation of burning, and occasions a slight vascularity in the part. Delphinia is said to be equally useful with veratria in tic douloureux, paralysis, and rheumatism, and to possess one advantage, namely, that it may be applied to the mucous membranes without producing the irritation so characteristic of veratria.

At present the chief use of staphisagria is for the destruction of pediculi.

14. Emetina is white, slightly bitter, very soluble in alcohol, sparingly so in water. Its composition is $C_{27}H_{27}O_{16}N$. It exists in the proportion of one per cent. in, and is the sole active principle of, ipecacuanha.

Ipecacuanha acts as an irritant locally when in contact with the mucous membranes: thus it produces vomiting, or catharsis, when and in some persons its dust, if inhaled in smallest quantities, excites a severe attack of spasmodic asthma. Remotely, ipecacuanha occasions increased secretion from the mucous surfaces, acting as an expectorant and as a diaphoretic; it acts besides upon the nervous system as a sedative or narcotic. This combination of sedative properties with the power of increasing secretion from mucous surfaces, renders ipecacuanha, or its active portion, a most valuable remedy in the earlier stages of inflammation of the mucous membranes of the bowels and lungs, and in certain spasmodic affections relievable by free discharges of mucus, as asthma and hooping cough.

Ipecacuanha is of daily use as an emetic, not only as an evacuant, but as a means also of checking in time many febrile disturbances. By it may the paroxysms of ague sometimes be stopped at once; by it may, in my belief, the accession of the eruptive fevers be arrested, or much mitigated; and by it may some forms of peritonitis be prevented or controlled. Nothing surpasses ipecacuanha in dysentery and other inflammatory affections of the bowels. But all the special adaptations of this remedy cannot be enumerated: its utility in some cases of hæmorrhage alone deserves mention further; and with the enumeration of the forms in which it is used I shall conclude this notice of a most admirable remedy: these are a wine, a simple and a compound powder, and a compound pill.

The last section of the alkaline bases are volatile, and appear in the form of a transparent, oily fluid. Two are mentioned as the active principles of officinal plants, namely, nicotine and conia.

15. Nicotine, the efficient part of tobacco, is an oleaginous, colourless liquid, soluble in ether and alcohol. It is heavier than water, but miscible with it; its taste is acrid and burning, communicable to 10,000 times its volume of water; its odour is pungent, and is that of tobacco. It is strongly alkaline, forming salts very soluble in water, varying, however, in their tendency to crystallize. Nicotina is spoken of as a frightful poison; it exists in tobacco in the proportion of from three to ten or twelve parts in the thousand. The fraction of a grain will kill a rabbit; a single grain placed upon the tongue will destroy a dog; and a small quantity introduced beneath the skin

acts with greater rapidity than prussic acid, killing one of these animals in an instant. The

symbol is N; its formula is $C^{10}H^8N$.

The effect of tobacco locally is that of a powerful stimulant, as we see exemplified when in the form of snuff, applied to the nostril, it occasions sneezing; or, when chewed, it excites the salivary glands; the effect remotely is that of a stimulant and sedative. It produces in those accustomed to its use a feeling of general tranquillity; it allays hunger, it overcomes fatigue, and it calms irritability. Under its influence the kidneys and the bowels perform their functions more freely. In those not accustomed to its use it produces sickness, fainting, anæmia, great coldness, and depression; and, if taken in large quantity, tremors, lethargy, and death. Its operation varies, as it may be exhibited either in the form of infusion or in that of smoke. When injected into the bowels in the officinal form of an enema, it produces faintness and depression; when smoked, it occasions the pathological states of vomiting, tremors, and lethargy. The disorders in which it is recommended are chiefly spasmodic, or in which it is supposed to relax the fibre; as, for example, in strangulated hernia, in constipation of the bowels, with distension of the intestines, and vomiting, as in ileus, or the advanced stages of peritonitis. In retention of urine and other spasmodic affections of the urethra, as also in tetanus, it has afforded effectual relief in some cases.

Tobacco is a ready poison to the inferior animals, and quickly will destroy pediculi; but its external employment is not in younger persons, at any rate, free from risk or danger.

The only officinal preparation is the enema tabaci.

16. Conia, the volatile, oily principle of the conium, may be produced by adding a fixed alkali to the seeds, leaf, or extract of conium, and then distilling. This alkaloid has an intense, suffocating vapour, and an acrid, benumbing taste; it is colourless at first, but afterwards becomes of a light brown; it is a powerful poison.

To Professor Christison is due the merit of studying more accurately than had been done previously the effects of this substance. He considers that when it destroys life it does so by paralyzing the muscles of respiration, exhausting the nervous energy of the spinal chord without affecting the heart, exciting spasms, or occasioning insensibility.

The diseases in which conium has been found useful are irritation of the mucous membrane of the lungs, carcinoma of the uterus, irritable ulcers, in some forms of spasmodic and neuralgic affections, and in acute rheumatism.

Conium is employed advantageously as a sedative and discutient in some painful but not malignant glandular enlargements.

The dried leaf, an extract, a tincture, the cataplasm, and the compound pill, are the officinal preparations of this plant.

With conium I conclude my first class, which comprises those drugs which owe their activity to an alkaloid. It contains some of the most powerful of the medicinal agents with which we are acquainted. The individuals, indeed, which compose it form a most interesting group, physiologically, as well as constitute a highly energetic body of therapeutical substances. They all yield principles containing nitrogen; oxygen is wanting in one—in nicotine; and this, in seeming obedience to a law, holds deadly enmity to life. The alkaloids possess great powers of attraction; pertinaciously resisting decomposing agencies. Orfila has shown that morphia placed for months in the midst of putrefying animal substances remains itself unchanged. The disulphate of quina is, in truth, an antiseptic. We see the powers of digestion resisted in the instance of strychnia, conia, and nicotine, since the blood of animals to which they have been administered either yields those principles or is itself specifically poisonous. Quina, further, resists the process of excretion in addition, as it may be found

in the urine and perspiration of persons taking it by the mouth.

Many of the alkaloids, again, can bear unaltered an elevated temperature, are sublimed unchanged; hence are made available as remedies in the gaseous form, as we see exemplified in the practice of smoking opium, tobacco stramonium, hyoscyamus, and digitalis.

Some few act as local irritants, as veratria, delphinia, and colchicia. One, emetina, would seem to act remotely as an irritant to the lungs. All, however, act upon the brain or nervous system with more or less activity, in whatsoever way they may be brought into contact with the body. Then thus circulating, we cannot but be struck with the diversity of their operation. Paralyzed limbs are forced to move, the voluntary muscles obey another power than the will, the involuntary muscles even are thus brought within our control, tone may be imparted, vital movements restrained, or contractility be annihilated. Consciousness again may be suspended, new and peculiar sensations induced, or sensibility wholly destroyed. All the nervous centres and their functions may be shown to be directly affected by the circulating fluid thus impregnated. Time does not permit me to enter further into this part of my subject; suffice it that some change must be effected in the nervous tissue by the formation of new or the transformation of the existing nervous matter, an observation of Professor Liebig, who has pointed out to us the fact that the vegetable bases containing nitrogen are of all the constituents of the body alone related in composition to that of the brain and nerves. What the exact change may be we are yet in doubt, but this we may hope eventually to discover by further improvement in chemistry, by reasoning, and by experiment.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILLSHIRE, M.D. (Edin.), M.B.S., Physician to the Royal Infirmary for Children, &c.

(Continued from page 487.)

GENTLEMEN,—I shall to-day occupy your time in considering the treatment of *tuberculous meningitis*. At the commencement I am forced into the melancholy duty of informing you that, with the exception, perhaps, of pulmonary tuberculosis, there exists no disorder in combating which the resources of our art are more generally found unavailing. Yet this, though it be true, must not force you to the bedside as men without action; though disheartening, it must not paralyze all effort. When you can do good it will be by at once, at the onset of the malady, bracing up your powers and rousing your energies in the endeavouring to put a barrier to the onward progression of this much-dreaded disease. In talking to you of the treatment of it, I cannot better introduce the subject than with the emphatic word "beware!"—beware of not early diagnosing the nature of the affection—beware of not at once evincing decided behaviour. If the malady is not thus early made out, and then promptly treated, woe be unto the little sufferer of this lethal disease! Bad as I have told you its prognosis is, and unavailing in most cases all attempts at its cure, still I cannot go to that extent to which some, like Rilliet and Barthez, proceed when they say, "For our part we have never seen a single case of tuberculous meningitis terminate in a cure, and our experience confirms that of Ruz, Piet, Gerhard, Green, &c."

On the contrary, I believe that the disorder may be now and then cut short in its progress if the steps which it has already made be but few or initial. I am of opinion that cases will occur in which, by early attending to the indications and promptly acting on them, you may save the life of the child. One thing I am aware of, and I am bound to tell you of it: it is this:—That many of those cases which I could produce as having been satisfactorily treated would be affirmed to be, by the writers I have just alluded to, either as

cases of certainly not developed tuberculous meningitis, but of simple meningitis of a sub-acute form, or else the less severe examples, merely ones of cerebral congestion or irritation of the nervous centre, &c. All I can say is this, that I have been most careful in endeavouring to diagnose the disorder, and my opinion is, that these cases have been, in the one class—though very limited I confess—cases of developed tuberculous meningitis in its first stage; the other, the more frequent premonitory state of disorder which, if allowed to run on, would be in all probability followed by that disease. To express my opinion of the numerical relation of these cases to the fatal ones, from the notes I have by me, it would be in the ratio of about thirty per cent., in which the disease has been attacked and ward off when only advanced to the premonitory form, and six per cent. of cases of averted fatality after *stupor* had been seen. This is about the ratio I would lay down, for, although I have not had a hundred cases to treat, yet, from what I have, this is the proportion. The great doubt, of course, will be with the first class of cases, as to what was really the nature of the disorder. I believe it to have been such as I have told you, and, if I am wrong, all I can say is, with Dr. Yeats, that "I confess I would much rather incur the charge of having twenty times supposed cases of water on the brain by attacking what I consider to be the early symptoms than once ultimately become a witness to this distressing scene by neglect, oversight, or mistake."

In relation to acute hydrocephalus, as to most maladies, the treatment may be said to be both preventive and curative. Of the latter I shall speak first. This, of course, has varied in the hands of practitioners, according to the peculiar views they held as to the nature of the disease, or according to what lesion, observed after death, was supposed to be, in the generality of cases, the cause of the fatal event. Those who have regarded the disease as essentially inflammatory, or as killing by the meningeal and cerebral congestion, by the exudation of lymph &c., at the base, and by the softening thought to be produced by inflammation, have treated the affection by purely antiphlogistic means. Those who have regarded it as a dropsy, or as essentially consisting in the phenomenon of ventricular effusion, have also treated it partly by antiphlogistic measures which would prevent such effusion, and partly by others which would cause such effusion to be absorbed or disappear. In modern times, however, a modified treatment has been adopted: for whilst it has been admitted that cerebral or meningeal congestion or inflammation form common elements in the series of phenomena, and have to be treated, yet it has been at the same time affirmed that a still more fundamental element exists, and to which attention is to be directed; and not only this, but that the origin, type, course, and effects of the—in most cases secondary—inflammation are of such a character as to oblige us to view it, in relation to its treatment, in a different manner to what we do inflammation of an ordinary form.

If you take the term *hydrocephalus* in its very loose, though very frequently adopted, sense, and ask which has been the more successful of these modes of treatment, you must be told that the first or antiphlogistic mode has been the one. But I have already pointed out to you the source of a great fallacy in respect to this point, viz., that those cases of so-called hydrocephalus so successfully treated by the antiphlogistic method have not been those cases to which the term *hydrocephalus* in its more limited, though appropriate, sense is applicable, or, rather, have not been cases of tuberculous, but, on the contrary, ones of simple meningitis, which is a different disease altogether. In those cases, however, in which the antiphlogistic method has been followed, and, even according to its most strenuous advocates, has failed, we have every reason to believe that most of them were examples of our present malady. Of course, if a person says, all forms of hydrocephalus are only different varieties of simple inflammation of the membranes

of the brain, or of the latter, and must be treated accordingly, I can only say here that such an opinion is a sad mistake. As this method of treatment, as well as some others, has been applied indiscriminately to both classes of meningitic and cerebral disorder, though only useful in one, I shall presently speak more in detail concerning them. At present I shall speak to you of that method of curative procedure I would advise you to follow.

You must remember you have two elements, if I may so call them, to treat in the disorder:—1st, the scrofulous, which evinces itself by the tubercular deposit, by the softening of the cerebral centres and the ventricular effusion; and the inflammatory, which proves its existence by the vascular congestion, the concrete or gelatiniform exudation, &c. You must also remember that this latter, the inflammation, in one sense is but an effect of the former: it is scrofulous inflammation, or inflammation of a peculiar character. These three great points must be regarded in your treatment. In one class of cases you will have the former, or the scrofulous element, making way for some time before the inflammatory phase of the disorder presents itself, or in others the latter is never seen at all; in another class, you will have the disease only made known to you by the prominence of the intercurrent inflammation; whilst in a third, you may believe that the latter precedes all the other elements of the disorder. Still this inflammation is soon followed by the tuberculous deposit, &c., and is always of a scrofulous character.

The symptomatic phenomena of every case will be those of irritation and pressure of the nervous centres, variously combined, and each of different degrees of intensity, according to the particular case. These symptoms I have already spoken of.

Now, suppose you are early called to a case in which either you dread the temporary congestion or vascular irritation of the membranes, &c., may be followed by the more marked characteristics of the true disorder, or in which you fear tuberculous exudation has commenced and has given rise to prominent signs of such irritation, you will at once have recourse to those measures which will diminish the vascular excitement: most carefully remembering, however, that the vascular excitement cannot be reduced in the same simple way as you would reduce common inflammation, and this for two reasons—first, it is of a subdued, asthenic, and specific type—it is, in fact, inflammation or congestion occurring in a scrofulous individual; secondly, the pushing of antiphlogistic measures to extremes would only still further incline to the outbreak of the other scrofulous manifestations—the tuberculous exudation, the serous effusion, the softening of the centre. You will have, then, to be careful in subduing the vascular excitement in question. In most cases, unless the child be very weak, very scrofulous-looking, and if you are called early, you are to apply leeches behind the ears; you must dry-cup at the nape of the neck, and purge pretty freely; have the hair cut quite close; prohibit the wearing of caps, &c.; have the child kept in a dark, cool room, with its head raised on a hard pillow, and its feet and legs clothed in worsted socks, and lint dipped in cold water applied to the forehead. You are aware of the obstinate constipation which exists in this disorder, and of the very great difficulty we have in overcoming it. There is also so much sickness, too, that the medicines will be repeatedly rejected. I advise you then, at the same time that you give (by mouth) *aloes* and *sulphate of potash*—for I have found them the best—in properly graduated doses, according to the age, that you have administered injections of *castor-oil* with *turpentine*, and the powders and injections repeated every three or four hours, until several evacuations are obtained. Do not be afraid of the *aloes* taking too long a time to act, as resinous purgatives are supposed to do: it will act as soon and better than most other things; and you will

find the turpentine an admirable derivative from the brain. In some cases you cannot dry-cup behind the neck, it would cause such excitement in the child, and you would do more harm than good; if you cannot, apply mustard poultices there instead.

Suppose, however, that the child, when first seen by you, does not present much evidence of inflammation or congestion; suppose that the symptoms of pressure are the more prominent, that with the symptoms of the first stage there is considerable tendency to sleep or stupor: here you will do no good by leeches, and they may be set aside altogether. But purge freely as before, have the head shaved, and rub in the *iodine ointment* night and morning all over the shaven scalp; put a blister behind each ear, and either dry-cup at the nape, or put mustard cataplasms there, as before recommended, attending, of course, to the same hygienic arrangement, &c., previously mentioned.

Now, the question is, in the early stages of *tuberculous meningitis*, after attending to the counter-irritation, purging, &c., and local depletion when advisable, what else are we to do? Are we not to endeavour to affect the system by some internal remedies, such as *mercury*, *antimony*, *iodine*, &c.? All these, and other things, as I shall soon inform you, have been advised.

What I advise you to do, is to give the child the *iodide of potassium*, and *iodine*, internally, whilst you are rubbing the *iodine ointment* freely over the scalp. To the youngest child you may give a grain of the *iodide* with 1-10th of *iodine*, every three hours. In this severe malady, it is only up to a certain point in its progress, as I have told you, that you can hope to do any good, and this point is the end of the first stage, for as soon as stupor comes on, as soon as the second period is entered, as I have before said, ninety-four cases out of one hundred will pass on to a fatal event. So long, however, as there is only constipation, vomiting, listlessness, and cephalalgia, with heat of head and slight tendency to sleep, you are privileged in looking for a more favourable termination.

On reviewing my notes for what has been the more essential points of treatment in such favourable cases, I am more inclined to place confidence in free purging, by the turpentine injections, and powder of *aloes*, blistering behind the ears, and the rubbing in of the *iodine ointment* freely over the shaven scalp.

You may make slight variations, if you like, in some of the purging agents. I have used *scammony*, *calomel*, and *rhubarb*, together, with good effect. You may also put a blister, in older children, at the nape of the neck, instead of behind the ears. Internally you may give the *nitrate of potash*, if full doses, or two grains of *calomel* with one of *ipeacacuanha*, every two hours, in lieu of the *iodine* mixture I before spoke of. All these means I have repeatedly tried, but I lay more stress upon the purging, blistering behind the ears, and application to the shaven scalp, than to anything else.

When stupor has come, when the second stage progresses, the above measures are still to be continued, the blisters behind the ears being kept freely open; towards the end of this stage a blister may be applied over the whole head.

Towards the third stage, if the child can be made to swallow, which it generally cannot do when that stage is completely attained, gentle stimulants, such as *ammonia* or a few drops of *ether*, may be administered, and turpentine injections repeated as before; warmth must be applied to the extremities. Up to the last moment, I never consider myself justified in standing by the bedside, and letting the child die without making some endeavours, although I too well know how unavailing they will be. In these cases, however, the inability of the child to swallow; the dislike of the parents to see the child forced, as it were, to suffer that which they believe will be unavailing; the refusal to allow blisters to be placed on the vertex or nape of the neck, or of cupping to be performed at the latter spot, place serious obstacles to our endeavours.

In some few cases, in older children, I have blistered the scalp and dressed it afterwards with antimony ointment, and for a short time it has aroused the power of the patient, soon afterwards, however, to sink. In other cases I have purged very actively with strong agents like *calomel*, and for the time with good effect. In one or two I have given the *biniodide of mercury*, but with no especial benefit; and, although I cannot say I have from the beginning tried a stimulating plan, yet I have employed it from the commencement of the second stage, and found it as unavailing as any other.

In the two cases I before alluded to, in which the children got better after stupor had come on, free purging by turpentine injections, blistering the scalp and behind the ears, in one case, and in the other purging by *aloes* and rubbing in *iodine ointment* on the scalp, with, internally, *calomel* and *ipeacacuanha* at first, afterwards the *iodine* mixture, were the means employed. Such are the principles of treatment upon which I would recommend you to proceed. At my next lecture I shall speak to you of other methods which have been followed.

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART XII.

PHYSIOLOGICAL ACTION OF THE ELECTRIC CURRENT.

Galvani discovered, in the course of his experiments on the electricity of metals, that muscular contractions are excited in the leg of a frog, recently killed and prepared, in the manner described in a preceding paragraph, when two metals, zinc and silver, for instance, and of which the one touches the crural nerve, and the other the muscles to which this nerve is distributed, are brought into contact with one another (a).

Galvani interpreted this fact by assuming the existence of an animal electricity, which the metallic arch simply serves to discharge. Volta having subsequently demonstrated, however, that the muscular contractions witnessed in Galvani's experiments are attributable solely to the electricity evolved by the contact of the two metals, and passing along the nerves and muscles of the animal, the notion of animal electricity was universally abandoned. In the paragraphs immediately preceding this it has been shown in what animal electricity really consists; it must be admitted that Galvani was by no means wrong in assuming its existence, since a great many phenomena and facts, discovered by that distinguished philosopher, are most certainly attributable to the electricity proper of animals.

The contractions excited in the frog or any other animal, living or recently killed, when the electric current passes through one of its nerves, are, however, altogether independent of this animal electricity. With the examination of this fact we will now commence our remarks on the action of electricity upon animals.

During the first years immediately succeeding the discoveries of Galvani and Volta, every journal, and every treatise on physics, teemed with particulars regarding the action of galvanism. The convulsions and starts exhibited by recently-killed animals, when submitted to the action of a sufficiently energetic electric current, even induced for a moment the extravagant hope that the new agent could restore the dead to life. This illusion, of course, vanished speedily, and science re-entered within its proper limits. Vally Lehot, Humboldt, Aldini, Bellingieri, and Marinini, and, more recently, Nobili, have studied the physiological action of the electric current. It would, of course, lead us too far to report the divers experiments made by these philosophers:

(a) The discovery of this fact is found mentioned first in one of Galvani's manuscripts, entitled, "Experiments on the Electricity of the Metals," and bearing date the 20th of September, 1786.

a simple statement of the facts that are well established in the actual state of the science will suffice.

If the sciatic nerve of the thighs of a rabbit (firmly fixed upon a table by its paws) be laid bare, carefully separated from the surrounding parts, wiped with unsized paper, and completely insulated from the neighbouring tissues by placing under it a band of taffeta induced with gum—and if the electric current produced by a pile of ten elements be then made to pass along the nerve, by applying to it the two conductors, at a trifling distance from one another, so as to send the current in the direction of from the central part to the periphery of the nerve—the thigh muscles of the animal will contract at the moment that the circle is closed, the back will become strongly bent, the animal will shake its ears and emit cries indicative of acute suffering.

The same phenomena will be observed if the respective position of the electrodes be changed—in other terms, if the current be made to pass in the reverse direction, viz., from the periphery to the centre of the nerve; they will be reproduced at the moment that the circuit is broken by interrupting the communication of the conductor with the nerve, no matter whether the direction of the current be *direct* (from the centre to the periphery of the nerve), or *inverse* (from the periphery to the centre).

But whilst the circuit is closed the animal will not exhibit any of these phenomena, no matter what the direction of the current may happen to be.

If the current be applied in a manner to traverse the nerve right across, instead of passing along it, the muscular contractions will be less marked, and even altogether missing whenever the experiment happens to be conducted skilfully enough to send the whole of the current into the nerve in the desired direction.

When repeating these experiments upon divers animals, it will be generally found that the signs of pain manifested by the animal are the most marked at the commencement of the passage of the inverse current, whilst the most energetic contractions will be observed during the first instants of the passage of the direct current. Marianini observed, that if the circuit of a pile composed of a certain number of elements is closed by touching the one pole with one, and the other with the other, hand, the strongest shocks invariably felt in the arm in which the direct current circulates.

Long-continued experimentation upon one and the same animal terminates in the disappearance of the whole of the phenomena described; and this will be the case the more speedily, the more energetic the current happens to be. If the animal be then allowed to rest for some time, or if the force of the pile be increased, the former phenomena will make their reappearance.

If we study the phenomena as they successively occur, in a prolonged series of experiments down to the time of their total cessation from exhaustion, we find that, upon interrupting the direct current, the contractions of the inferior muscles (i. e., the muscles below that point of the nerve where the current is inserted) grow more and more feeble, whilst they continue still unimpaired in the muscles of the back, and whilst the agitation and, frequently, the cries of the animal persist. We find, also, that the effects of the direct current are limited during the first instants of its passage to the contractions of the inferior muscles. With the inverse current, the contractions of the muscles of the back, the cries and shaking of the ears, are, after a time, observed only at the moment that the circle is closed, at the same time the contractions of the inferior muscles are hardly perceptible; upon the interruption of the inverse current, on the contrary, the latter muscles are still found to contract, whilst contraction in the muscles of the back, emission of cries, and shaking of the ears have ceased to make their appearance.

There are, accordingly, two distinct periods in the action of the electric current upon the nerves of a living animal. In the first

period the irritation of the nerve is transmitted in all directions, towards the centre as well as towards the periphery, at the commencement of the action as well as at the end; and this independently of the direction of the current. In the second period, the excitation of the nerve is communicated towards the periphery, during the first instants of the action of the direct, and at the moment of the interruption of the inverse, current; the irritation of the nerve is, on the contrary, transmitted towards the brain when the direct current is interrupted, or the inverse closed.

The preceding results may be expressed in more simple terms, viz.—the current acts in the sense of its direction when it commences, and in the opposite sense when it ceases, to circulate in the nerve.

The contractions of the muscles of the back and head are induced by reflex action of the spinal marrow. Upon subjecting rabbits recently killed, and prepared as in the preceding experiments, to the action of a single element or simple circle, the inferior muscles are observed to contract at the moment of closing the circle of the direct, or breaking that of the inverse, current. When employing a more powerful pile, the same muscles are found to contract both at the commencement and cessation of the circulation of the current, and this altogether irrespective of the direction of the latter. After the experiment has continued for some time, the contractions are observed only at the commencement of the action of the direct, and cessation of that of the inverse, current.

These phenomena are the same for all animals, but they are most clearly perceptible with frogs. Experiments with the latter animal show that it is not only a galvanoscope of most perfect susceptibility, but that it may be looked upon, moreover, as an instrument fit to do the office of a galvanometer, and to indicate, the direction of the current circulating in a portion of its nerves.

Marianini was the first to observe that contractions are obtained at the moment of breaking the circle, without there being any at the moment of closing it. To succeed in this experiment, it suffices to introduce a frog into the circuit of a pile, and to close the latter by touching one of the poles with one hand, and immersing the fingers of the other hand in the liquid in which one of the extremities of the frog is placed. During the first instants the current is very feeble, owing to the low conducting power of the hand; but it increases in proportion as the fingers get more and more moistened with the liquid, and it may then be observed that no contractions take place at the moment of the introduction of the current, whilst they are found to manifest themselves at the moment of interrupting the current.

We have to add here a few words on the action of the electric current upon the muscular fibre freed from nervous substance—as far, at least, as this can be effected. The result of several experiments in this respect would lead to the conclusion that the electric current acting upon a muscular mass excites contractions, both at the moment of closing and at that of breaking the current,—no matter what the direction of the current may be with respect to that of the muscular fibrils,—and that the contractions which take place upon breaking the current are the first to disappear.

We have now to treat of certain circumstances which modify the action of the electric current upon the nerves and muscles of living, or recently-killed animals.

The phenomenon called the *voltic alternations* consists in this:—If a frog, prepared in the usual manner, is placed astride on two small glasses containing either pure or slightly saline water, so that the spinal marrow plunges into the one, and the legs into the other, glass, and the circuit is then closed, allowed to circulate for a certain time (say twenty or thirty minutes, according to its force), subsequently interrupted and then closed again, no new contractions are

obtained, but they make their reappearance if the direction of the current is reversed; they cease again to manifest themselves after the current has been made to proceed a certain time (less than at first) in the new direction, and reappear upon re-establishing the original direction of the current. These alternations may be repeated a certain number of times upon the same animal. The intervals of time required to elapse between the passage of the one and that of the other current depend upon the intensity of the current and the vitality of the animal.

It is easy to demonstrate experimentally that the weakening of the excitability of the nerve by the circulation of the current is most manifest in the portion more immediately traversed by the latter. If, after having passed a current through the nerve of a frog until contractions have ceased to manifest themselves, the conductors are applied to another portion of the nerve further removed from the brain than that acted upon at first, the contractions are immediately seen to reappear. Pursuing this experiment still further, other portions of the nerve still further distant from the brain may be laid bare and acted upon with the same results. It might accordingly be said that the excitability of a nerve aroused by the electric current withdraws towards the periphery of the nerve in proportion as the vitality of the latter becomes more and more extinct.

The author has made a series of experiments, with a view to ascertain how the electric current acts upon animals destroyed by poison. The results of these experiments tend to show that the action of the electric current upon the nerves of animals which have perished in hydrogen, nitrogen, carbonic acid, or chlorine, presents no difference from that upon animals which have not been subjected to the influence of these gases. But it is not the same with animals destroyed by hydrocyanic acid, or killed by repeated discharges of a strong battery across the spinal marrow. A current produced by one or even by several elements, and applied to the nerves of such animals, fails to excite muscular contraction, or, if there happen to be some slight contractions, they cease entirely after a few seconds. The muscles, however, give very marked signs of contraction when subjected to the same current, which is another proof that the muscular fibre possesses the property to contract under the influence of the electric current, independently of the nerve. The action of the electric current upon animals that have perished in sulphuretted hydrogen excites no contraction, except the current be very powerful, and even in that case the contractions cease speedily.

If an electric current is made to pass through a carefully insulated and tied nerve, above the ligature, it produces the effects of its action on the nervous centres, whilst, if applied below the ligature, it produces the effects of its action on the extremities of the nerves. But if the two poles of the circle be applied, the one above, the other below, the ligature, the phenomena will be the same as if the ligature did not exist, or they will, at all events, simply be less marked, since the current in that case is by no means interrupted, but simply weakened in its action.

From a series of experiments made by the author, it results that the excitability of a nerve is reduced much more by the passage of the direct, than by that of the inverse, current—nay, even, that the inverse current heightens the excitability of the nerve, as the following fact tends to prove:—

If the inverse current is made to pass through the nerve for two, three, or four hours, it happens, in the great majority of cases, that, at the moment of breaking the circuit, the limb to which that nerve is distributed suffers a very violent contraction, which lasts a certain number of seconds, and might, not inappropriately, be called tetanic. It suffices to close the circle again, to put an end to this tetanic tension; but (and this is most important and remarkable) the reclosing of the circle is attended with another contraction, after which the limb returns to the natural state. This contraction had ceased to manifest itself at the

commencement of the experiment, and makes thus its reappearance after the long-continued action of the inverse current.

The results of a great number of experiments made by the author, with a view to determine the force of contraction elicited by the electric current in different cases have led him to the following general conclusions. (The author used in these experiments an apparatus constructed by Bréguet):—

1. The contraction excited by the transmission of an electric current through a nerve in the sense of its ramification, and which, for that reason, is termed *direct current*, is invariably more energetic than that excited by the same current proceeding in a direction opposite to that of the ramification of the nerve (*inverse current*).

2. The direct current weakens and destroys speedily the excitability of a nerve, whilst the passage of the inverse current, on the contrary, augments this excitability within certain limits.

3. To produce these effects it is necessary both for the direct and inverse current to continue their action upon the nerve for a certain time, and this the longer the lower the degree of excitability possessed by the nerve acted upon.

With regard to the influence of rest upon a nerve that has been subjected to the action of the electric current, the author has ascertained that rest restores a portion of the lost excitability to the nerve through which the direct current has passed; whilst, on the contrary, it deprives a nerve through which the inverse current has passed of a portion of the excitability which it had acquired under the influence of this current. With a very irritable nerve a short rest suffices for either purpose; the duration of rest required to restore the excitability lost by the passage of the direct, or to carry off again that acquired under the influence of the inverse, current augments in proportion as the nerve acted upon possesses less excitability.

Upon the preceding facts the author bases the following theory of the action of the electric current upon the nerves, and of the phenomena produced by this current in animals:—

The passage or circulation of the electric current in the nerves produces no other effect except to modify the excitability of these organs. The muscular contraction is invariably excited by the effect of the *electric discharge*, properly so called. Every one knows that a spark is produced both by the closing and interruption of the circle of a pile; and it is precisely at the moment of closing or of breaking the circle that muscular contractions are manifested. A very small discharge from a Leyden jar suffices to excite muscular contractions in a frog; a jar that has been already discharged several times, and can consequently retain but a very trifling amount of electricity, is still capable of producing fifteen or twenty contractions in a frog.

When using the Leyden jar, the contraction excited by the inverse discharge ceases likewise more speedily than that excited by the direct discharge.

It is accordingly easy to understand why, the excitability of the nerve being diminished, the spark produced by the interruption of the direct current fails to excite renewed contractions. With the inverse current, the spark produced by the interruption of the current excites renewed contraction, because, during the interval of the circulation of the inverse current, the excitability of the nerve has increased. This augmentation of excitability ceases with the action of the current, and thus the spark produced by the subsequent closing of the inverse current fails to excite renewed contraction.

This theory explains likewise the phenomenon of voltaic alternations: when the direct current has circulated a long time in a nerve, and deadened the excitability of the latter, the spark produced by the closing or breaking of the circle fails to excite renewed contractions. The inverse current, which is subsequently applied, restores to the nerve a portion of the lost excitability, and the interruption of the circuit is ac-

cordingly attended with renewed muscular contraction. Upon returning afterwards to the direct current, the contractions obtained during the short time that the nerve preserves the excitability acquired by the previous passage of the inverse current are more energetic than the preceding ones (those excited by the interruption of the inverse current), since the direct current, when acting upon a nerve endowed with a certain degree of excitability, produces stronger contractions than the inverse current.

The results of some experiments made by the author would seem to show that the electric current produces neither contractions nor signs of pain, when applied to the cerebral hemispheres and to the cerebellum. However, if the conductors are made to touch the quadrigeminal tubercles, the pedicles of the brain, or the medulla oblongata, tolerably strong contractions are produced all over the body, and the animal gives signs of suffering.

The author and Longet have studied the action of the electric current on the roots of the spinal nerves and the fasciculi of the spinal marrow. They found that, when the interior or motory roots are acted upon, contractions ensue, during the first period, both upon closing and breaking the circle, no matter whether the current be direct or inverse; during the second period of excitability the action of the current upon the anterior nerves is the reverse of that upon the mixed nerves, viz., the *inverse* current excites contractions during the first instant of its circulation, but none at its interruption; whilst the *direct* current excites them at the moment of its interruption, but not at that of its commencement. The anterior fasciculi of the spinal marrow comport themselves in this respect like the corresponding roots.

With regard to the action of the electric current upon the nerves of the senses, Magendie caused the current to pass through the optic nerve of a live animal: he observed neither contractions nor signs of pain. When operating upon ourselves, by touching with the extremities of a pile, consisting of a single element, the ear and the eye, or the ear and the tongue, or the eye and the tongue, we perceive sensations of sound, flashes of light, and a peculiar taste. These effects can only be attributed to an action exercised by the current upon the sensory nerves of these organs, and not to contractions excited in their muscles; a very feeble current, quite incapable to excite even the most trifling muscular motions, has still the power to act upon the senses. Nor can we attribute the peculiar taste to an impression made upon the tongue by bodies resulting from galvanic decomposition of the salts of the saliva: since even a very feeble current, such as positively cannot effect this decomposition, creates still this peculiar electric sensation upon the tongue.

For the little we know regarding the action of the electric current upon the ganglionic system we are indebted to the celebrated Humboldt.

When the electric current is made to pass through the heart of a recently-killed animal, a few instants after the cessation of the pulsations, this organ is found to recover its usual motions a short time after the passage of the current, and to retain them for some time after it has been withdrawn from the electric influence.

If, instead of waiting for the entire cessation of the natural motions of the heart, the electric current is made to pass through this organ whilst its movements still continue (though enfeebled), the contractions grow more frequent after the current has circulated some time, and this augmentation persists a few instants after the interruption of the current. The electric current produces the same effects upon the peristaltic motion of the intestines.

Considering the vast importance of the ganglionic system in the performance of the organic functions of animals, this subject requires a much more extensive and profound study than has hitherto been bestowed upon it.

We have now still to examine the effects pro-

duced by electric currents interrupted and re-established at short intervals.

If a frog, prepared in the usual way, be fixed upon a table by means of small nails, to one of which one of the conductors of a pile is attached, and another of the nails be then touched repeatedly and at very short intervals with the other conductor, thus closing and interrupting the circle frequently within a very short space of time, the animal will be seen to stretch its limbs violently as in an attack of tetanic convulsions, no matter whether the current be direct or inverse.

The excitability of the nerves of a frog thus *tetanized* by the passage of the electric current is greatly reduced compared to that of the nerves of another frog which has been subjected to the action of the continuous current.

The author has made a great many comparative experiments on this subject. He took two frogs, prepared in the usual way, and subjected the one to the action of the continuous current produced by a pile of forty-five elements, the other to the action of a pile of equal force, but the current of which he frequently and at short intervals interrupted and re-established.

The experiment lasted from five to ten or fifteen minutes. Upon subjecting the two frogs subsequently to the action of an electric current applied to the lumbar nerves, the author found that it required a greater number of elements to excite contraction in the one that had been acted upon by the interrupted current than in the other which had been subjected to the action of the continuous current. He likewise subjected the two frogs, at one and the same time, to the action of a continuous current, and found the consequent diminution of excitability invariably greater in the former than in the latter.

The results of Marinini's experiments upon this subject correspond with those obtained by the author.

The reality of this great diminution of the excitability, or, to speak with greater precision, of the *nervous force*, caused by the action of a frequently-interrupted electric current, has been demonstrated most clearly by Masson's experiments, made with a peculiar apparatus, by means of which the electric current may be applied and interrupted a great many times at very short intervals. This apparatus consists of a metallic wheel resting upon a metallic axis, and made to revolve by means of a handle upon two pads covered with the usual amalgam; one of these pads is in communication with one of the poles of the pile, the other pole is in contact with a wire which is bent in a spiral round a cylinder of soft iron, and abuts at an immovable metallic linget pressing upon the cogs of the wheel.

When the wheel is made to revolve, the circle is closed each time the linget touches one of the cogs, and interrupted each time the linget comes in contact with one of the non-metallic interstices of the wheel. If the two extremities of the conductor are laid hold of with moistened hands, whilst the wheel is revolving, a series of violent shocks are felt. If the motion of the wheel is sufficiently rapid, these successive jerks produce a very painful tension in the arms; the experimentalist finds himself unable to quit his hold of the conductors, he clutches them, on the contrary, involuntarily and with great force.

By means of this apparatus, and a pile composed of a small number of elements, Masson succeeded to kill a cat in five or six minutes.

Masson found that the violent shocks and spasmodic tension disappear upon imparting to the wheel a very rapid motion. Pouillet has demonstrated that, when the duration of the interval between two discharges of the current is reduced to about 1-300th of a second, the interruptions are no longer distinguishable, and the effect is the same as that produced by a continuous current.

A rabbit subjected to the action of a pile of ten elements, discharged by means of Masson's wheel, dies in a few seconds. These powerful effects are no doubt to be attributed to the great

loss of nervous force suffered in a very short space of time.

We will conclude with a few remarks on the application of the electric current as a therapeutical agent.

Leaving out of the question all purely theoretical notions, it may be safely asserted that, in certain cases of paralysis, the nerves have suffered an alteration analogous to that produced by the continuous action of the direct electric current; now, it has been stated in the course of the preceding remarks, that the excitability of which the circulation of the direct current deprives a nerve is restored by subjecting the same nerve to the action of the inverse current.

To this may be added, that a limb, although paralyzed, exhibits invariably some contractions when subjected to the circulation of an electric current, or to the action of electric discharges; and these contractions favour the re-establishment of the functions of the muscle.

If the two sciatic nerves of a live frog be cut, and one of the legs be left at rest for ten, fifteen, or twenty days, whilst the other is subjected twice or three times a day to the action of an electric current, the latter will continue to contract, whilst the former will be found to have lost altogether the power of contracting under the influence of the electric current.

There are a few plain rules to be observed in the application of the electric current as a remedial agent in paralysis. A very feeble current only should be used at first. The author saw a paralytic patient seized by truly tetanic convulsions, upon the application of the current produced by one single element. The circulation of the current ought never to be continued over long, more particularly if the current happens to be energetic. The interrupted current is preferable to the continuous one; but the patient should be permitted to rest after having received from twenty to thirty shocks at the most.

A pile with Masson's wheel or, still better, the electro-magnetic machine may be considered the most convenient and best-adapted apparatus for the application of the electric current as a therapeutical agent in paralysis.

For conductors, two bands of sheet-lead or sheet-copper may be used; the extremities intended to be placed in contact with the skin, are to be covered with pieces of cloth impregnated with salt water.

In some cases it is judicious to use, for extremities of the conductors, needles such as are usually employed in acupuncture.

There are already on record a sufficient number of well-authenticated cases of cure of paralysis effected by the electric treatment, to encourage physicians and patients to persevere in the application of this treatment; without perseverance, it would be altogether vain to look for satisfactory results.

The application of the electric current has been recommended against tetanus.

This application is founded upon the following principle: a current circulating by jerks, during a certain time, in the nerves of an animal excites tetanic convulsions; a continuous direct current, on the contrary, occasions paralysis, sufficiently protracted. We are accordingly authorized to conclude, that the application of the continuous direct current to a tetanized limb will tend to destroy the tetanic state, by inducing a state more or less bordering on paralysis; and the correctness of this conclusion is, indeed, demonstrated by facts. When operating on frogs, tetanized by narcotics or by hydrocyanic acid the tetanic attack is found to give way under the influence of the protracted action of the direct current; the poisoned frogs die without exhibiting the usual convulsions.

The results of the application of the electric current in a case of tetanus (which application was made by the author himself, and the case reported by him in the "Bibliothèque Universelle," May, 1838—probably the first case of the kind recorded, in some measure, to confirm the correctness of the principle upon which the application is based. At the moment of the circulation of the

current, the patient felt no violent shocks, and was enabled to open and shut his mouth: the circulation of the blood and the functions of the kin seemed re-established. Unfortunately this amelioration did not last. The disease in this case was occasioned by the presence of foreign bodies in the muscles of the leg. Perhaps the results may prove more satisfactory in cases of tetanus occasioned by other causes than traumatic lesion. Moreover, though the electric current should simply prove a means to alleviate rightful sufferings attendant upon this cruel malady, even this would be matter for congratulation.

It has been recently proposed to apply the electric current as a means to dissolve stones in the bladder. But we need simply reflect that the substances composing urinary calculi are insoluble in water, to see at once that the electric current is inapplicable for this purpose. The electric current has, likewise, been recommended as a means to dissolve the cataract. To disprove this notion, it suffices to bear in mind that, if we change the position of the poles of a current that has been made to pass through a mass of albumen, we never find that the albumen which had coagulated at the positive, is redissolved at the negative, pole. It is, consequently, possible to create, but surely not to cure, a cataract by means of the electric current.

Petrequin, of Lyons, has recently proposed the application of galvano-acupuncture for the cure of certain aneurisms. The principle of this application seems to be based upon the property of the electric current to coagulate the albumen of the serum of the blood, and thus to fill in part the aneurismatic sac.

ORIGINAL CONTRIBUTIONS.

CASE OF DEATH FROM ARSENIC, MEDICINALLY ADMINISTERED IN SMALL, BUT LONG-CONTINUED, DOSES; IN OTHER WORDS, CASE OF SLOW POISONING BY ARSENIC.

By GEORGE S. HOOPER, M.D., Jersey.

Mr. —, aged fifty-four, of spare habit of body, had for ten years been afflicted with shaking palsy, for which, at various intervals, he had been subjected to many modes of treatment, with only temporary, if any, benefit. His habits of life were always intellectual and arduous from the age of twenty, at which time he entered the civil service of India, rising through its different grades up to the highest office. Since the commencement of his malady he was always able to command the best advice within his reach, and he gave a fair trial to every treatment which he underwent. In spite of these advantages, however, he grew gradually worse, but, nothing daunted by previous failures, he again proceeded to London to consult afresh upon his inveterate complaint. By the advice of a distinguished physician he commenced taking Fowler's arsenical solutions, at the dose of five minims, three times a day, continuing it from October — to the 24th of the following June, when he consulted me for ophthalmia of the left eye. Having been made aware of the treatment he had been and was still pursuing, and finding that this local affection had been preceded by general lassitude, and uneasiness in the fauces, I feared it might be the effect of the action of arsenic on the system, and under that impression recommended its being instantly discontinued. What followed too clearly proved that my fears were not without foundation. In less than twenty-four hours the conjunctiva and palpebre of the same eye became oedematous and of light livid redness, giving more the idea of congestion than active inflammation. No pain or aching in the globe of the eye. A very copious flow of tears accompanied the affection at this stage, and an equally abundant discharge of thin fluid, so like tears that the patient be-

lieved it was really the lachrymal secretion, took place from the corresponding nostril. On the third day erythematous inflammation broke out on the palpebre, extending over the left side of the nose, and rapidly spreading over the entire surface of that side of the head, not extending beyond the medial line. The redness and tumefaction on the one side formed a remarkable contrast with the natural appearance of the integument on the other, the separation being abrupt and distinct. The external ear was the only seat of pain, beyond a feeling of tension and tingling heat.

While the foregoing local affection was proceeding, the patient experienced headache, drowsiness, nausea, with an inexpressible feeling of anguish and prostration. At first the pulse was rather below the natural standard: subsequently it ranged between 90 and 100; the tongue was moist, free from fur, and uniformly natural and healthy in its appearance; the bowels were sluggish, but not more so than before the present attacks; respiration natural; animal heat preternaturally high. This last phenomenon, however, was habitual to him in what constituted his state of health. His hand always felt hot. He used to call this increased temperature his *Indian* heat; and it made him so insensible to external cold that an additional garment out of doors was to him intolerable in any weather. Indeed, he never wore any wrapper, except at the earnest request of his friends, who viewed his apparent fool-hardiness in that matter with concern and apprehension for the consequences.

As to the paralysis, it now became much worse. The muscular tremours, especially, were increased to an extreme degree: affecting the lower jaw, the neck, the back, and both arms, they became so uninterruptedly harassing that the poor sufferer was unable to maintain the same position more than a few minutes at a time, night or day; a more pitiable state could not be imagined. Almost driven to despair by the perpetual agitation and dragging of the muscles, he felt the drowsiness consequent to protracted insomnia and bodily exertion, and yet was he almost totally denied the soothing influence of sleep. In his own words, he was in a constant struggle between sleep and motion; and, even when he did dose for a few moments, that short respite was purchased at the dear price of increased irritability of the muscles on waking.

The erythema, having run through its different stages, left the skin numb and liable to become hot, red, and shining, from the least local stimulus or increase of vascular action. On the nose and ear especially the heat and tingling were at times most unpleasant. The ophthalmia, which, as before stated, ushered in the erythema, became more acute as the latter subsided; and the oedema of the conjunctiva soon exchanged its pale, flaccid, indolent character, for the deep red, fleshy, irritable surface of organized chemosis. After vain attempts to subdue this morbid action by scarifications, leeches, &c. &c., the cornea threatening more and more to pass into a state of irreparable disorganization, there remained no possible means of saving the eye except by the excision of the diseased conjunctiva all round the cornea, which operation was skilfully and successfully performed by my friend, Dr. H. Duval, a distinguished French oculist, who was on a professional visit to this island.

Six weeks had now elapsed, during which, owing to prostration, involuntary movements, and scarcely any sleep or rest of any kind, the sufferer's strength had, with great difficulty, been somewhat supported. He was allowed as much food as he could take, and he managed to take a good deal of one sort and another; but it was evident from his large alvine evacuations that digestion was but imperfectly performed. Hence little assimilation, and a gradual breaking down of the system, in spite of what appeared a sufficient quantity of food. Tonics were, of course, freely administered. The only medicines, however, which seemed for a while to bestow any sensible relief were carb. ferri with opium,

followed by O. ricini—the one being taken at night, the other the following morning, for several successive days. Under this treatment the patient was able to enjoy some sleep, and the aching of the muscles and general restlessness were certainly diminished. The hopes which this partial improvement suggested were, however, destined soon to vanish. Again the fauces became the seat of irritation, which rapidly extended to the larynx and trachea, causing a most troublesome hawking and cough, with ejection of phlegm in variable quantity. There was something very peculiar in this mucus: it was of a bright yellow colour, translucent, and readily soluble in water. When received in an empty glass, it adhered to its sides, spreading and drying up without losing its colour. In water it quickly vanished, merely tinging it with its colour.

Soon after this my wretched patient's appetite, or rather power to eat, completely failed him, and he sunk gradually till the 13th of September, when, in the full possession of his mental faculties, he welcomed death as the only relief from a state of bodily suffering never surpassed in severity, long continuance, and almost utter hopelessness.

REMARKS.

It might be justly said that, before commencing the arsenical treatment for his inveterate paralytic affection, the subject of the foregoing case was so sorely afflicted that to him life could have no attractions, and that, under such circumstances, any desperate attempt, with the view of curing or even alleviating his sufferings, was justifiable, both as regards patient and physician. Perhaps some such idea may have influenced both: for the patient himself had been repeatedly advised, by myself and some of the highest authorities in the profession in London, to give up all hopes of direct benefit from medicines, and to confine himself to paying great attention to diet, keeping his bowels in order, taking regular exercise in a carriage, and travelling during the fine season. If not to himself, however, his life was most valuable to his family in every respect: for, independently of pecuniary considerations, they had every advantage and assistance to look for from his strong mind, accomplishments, and thorough knowledge of the world—all which, fortunately, were in no way affected by his disease.

Arsenic, that most virulent of mineral poisons, having been stripped of part of its terrors by being ranged among the tonics, has, of late years, been rather freely administered as a remedy in neuralgic affections. Whether or not effects similar to those detailed in the preceding history have occurred under like circumstances; without being referred to the same cause, can only be conjectured as by no means impossible. There is, doubtless, a very natural disinclination in medical men to ascribe to the agency of drugs fatal terminations which may anywise be referred to the progress of disease. However, without questioning the remedial properties of arsenical preparations in certain diseases, it must be admitted that the properties they possess in common with tonics are secondary compared to their own specific action as poisons; and, therefore, the practical utility of such wholesale classification may be fairly doubted. The substances included under the head of tonics are, for the most part, innocuous in themselves, and might be taken in large quantities by a healthy person without any dangerous results. Under no circumstances were they ever known to accumulate in the system, and reverse or alter their ordinary mode of action by long-continued use. The latter property belongs essentially to the mineral under consideration, and to a few others, viz., mercury, lead, silver, and iodine, of which not only their use as medicines, but also the diseases incidental to certain trades, furnish abundant illustrations.

In the case before us, the arsenical solution was taken for an unusual length of time, viz., eight months and a half, in small doses, certainly, but without any cessation. Thus, at fifteen minims per diem, one pint of the solution, equal to sixty-four grains of arsenious acid, was

gradually instilled into the system! What portion of that quantity remained, and what portion was carried off with the secretions, it would be impossible to estimate with any degree of precision. Certain it is, however, that an accumulation did take place to some extent incompatible with the physiological state of the vital functions. Indeed, a review of the phenomena of this curious case would lead one to infer that a combination had taken place between the mineral and the structures of the body, and that, in particular, to its presence as a sulphuret was due the anomalous colour of the mucus, which was ejected from the fauces. I regret exceedingly that, owing to this inference not having occurred to me at the time, and having been suggested to me by my friend Dr. Magreight too late to enable me to ascertain whether chemical analysis would confirm it, the fact here stated loses much of its importance. Nevertheless, I hope this inference will not be considered as too far fetched, presented as it is rather as a scientific conjecture than a positive deduction.

The mode of administering arsenic in the treatment of chronic diseases is to begin by very minute doses, increasing them gradually until the intended effect be realized, or the signs of the full action of the remedy on the system forbid its being pushed any further. These signs are stiffness of the palpebre, heat and soreness of the tarsæ, and sometimes tenderness of the gums; by taking warning from which the practitioner may desist in time to avoid more serious injuries. From what occurred in the present instance, however, I should incline to think that the long-continued use of arsenical preparations in small doses may so insensibly impair health that, before the above signs are observable, the deleterious action which they indicate is already of too grave a nature to admit of being counteracted. Thus, Mr. — was not aware of any danger from the medicine which he was taking up to the time of its displaying its poisonous action on his system, by effects which showed themselves suddenly, and followed upon each other in rapid succession. Previously, instead of feeling worse, he thought himself better, and persevered in the treatment with increasing faith in its efficacy. But, alas! from that moment his hopes vanished before the two evident aggravation of his paralysis. He quickly lost all control over the muscular contractions of the upper extremities, and in a few days the agitation became incessant and general. Arsenic exerts a very remarkable action on the nervous centres; hence its rapid effects as a poison, not to say anything of those which it produces as a remedy in periodical headache and ague. It is well known that, when death takes place as a primary consequence of that poison, the local injuries in the stomach and bowels, or wherever it may have been deposited, do not alone sufficiently account for the fatal result. Was it the beneficial effects in the above-named diseases that suggested its use in the treatment of spasmodic affections, as the property of inducing erythema led to its internal use in the treatment of inveterate cutaneous diseases, such as lepra, psoriasis, icthyasis? Such generalizations would savour strongly of empiricism: for although *matrua medica* is, confessedly, much indebted to accident, and owes not all its lore to scientific research or analytical deductions, still it would be wrong to conclude on that account that we may try dangerous experiments with substances with whose mode of action on the body we are imperfectly, if not totally, unacquainted. From these considerations it appears to me that, in the present state of our knowledge, the preparations of arsenic cannot always be safely administered in those diseases for the cure of which they need to be exhibited for a lengthened period; and, consequently, that their use as remedies ought to be restricted to those diseases in which their efficacy may be fairly tested in a few days. A few cases like the preceding one would place that conclusion beyond all doubt; and, therefore, it is hoped that, should such have been observed by other practitioners, they will be laid before the profession in the same manner.

BLIGHTED OVUM SIMULATING POLYPUS OF THE UTERUS.

Communicated by S. W. J. MERRIMAN, M.D.
Brook-street.

In page 455 of your journal you give a short account of the extrusion by natural means of a polypus uteri, which is supposed to have existed for twelve months, and which the medical men in attendance were about to remove by a ligature. Whether a polypus can be strangulated by the contraction of the os uteri around its pedicle, though it has been asserted, may be doubted; but at all events the history of this case scarcely warrants such an opinion. Had the process of sloughing been going on, Dr. Johnson could scarcely have failed to recognise it; but the account adds that "the tumour had the appearance of bloody coagulum, and melted away, as it were, under the touch:" this certainly is not the character of a polypous tumour, but resembles much more a formation the result of conception. I have in my possession, from the minutes of a former physician-accoucheur to the Westminster General Dispensary, an account of a tumour which was considered to be a polypus, but proved, when brought away by the finger, to be a blighted ovum. As I believe it to be an analogous case to Dr. Johnson's, I beg to transcribe it for the benefit of your readers:—

"Mrs. Streeter, one of the most intelligent and respectable midwives of the Westminster General Dispensary, called upon me, and begged me very earnestly to visit one of her private patients who lived in Porter-street, Leicester-square, and whose case she thought a very alarming one. She particularly begged that I would see the patient that same evening, stating that she was suffering very much from uterine hemorrhage: accordingly I went. After making various inquiries, and having been told that this hemorrhage had been going on, more or less, for three or four months, I proceeded to make an examination *per vaginam*, and found the os uteri considerably open, and encircling a round bulging substance which I supposed to be a polypus, and partly withdrew my finger, intending to announce that there was a polypus, which must be tied and brought away; before I had quite withdrawn my finger, however, I determined to examine the tumour again, and, passing my finger more within the edge of the os uteri, I thought I felt an indentation on compressing the tumour. This led me to make a more minute investigation, and I was aware that I could dislodge the substance, which I still supposed to be a polypus, by the aid of my finger only. This, then, I effected, and, having brought the tumour into the light, discovered that it was not a polypus, but a blighted ovum, which, according to the midwife's account, must have been retained in the uterus nearly five months.

"When I had explained the case to my patient, and congratulated her upon having got rid of her malady, the midwife said that she must apologize for not having told me all the circumstances of the case, which were these: that the patient had been seen by another accoucheur of eminence, who had pronounced the case to be a polypus, round which he had proposed to pass a ligature, and had appointed the next morning for performing the operation; and this was the reason why I was so urgently desired to see the patient that evening, her friends having considered that it would be desirable to have another opinion upon the nature of the case before she submitted to what they expected to be a very formidable operation.

"I thought it right to state to the patient and her friends very expressly that I was just about to pronounce the very same opinion of the nature of the tumour, and to propose the same mode of removing it; but, under a wish of being quite correct, I examined again, and then found that I could at once remove it, and that probably the examination which the other gentleman had made had occasioned the uterus to sink lower into the pelvis, and thus had brought the parts into a position for a more accurate examination."

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of Aug. 9; M. BRONGNIART in the chair.

INFLAMMATION OF THE SHEATHS OF TENDONS AFTER AMPUTATION.—M. Robert, interne of the hospitals of Paris, forwarded a paper on the inflammatory accidents which may result from section of the tendinous sheaths after operation, and on the mechanism of their production. M. Robert concludes, from numerous experiments, that, after division of a tendon, it rises in its sheath, and, by a sort of suction, aspirates any fluid, such as blood or pus, which may be in the neighbourhood of the wound; the presence of this foreign body in the sheath explains its subsequent irritation, and would, according to M. Robert, be prevented by a ligature placed on the sheath in such a manner as to procure its obliteration.

COMPOSITION OF THE INTESTINAL SECRETIONS IN CHOLERA.—Professor Andral stated that the rice-water secretions found in the intestines of patients affected with cholera had been the object of his researches. Hitherto they were looked upon as composed of the elements of the blood—albumen and serum being asserted to exist in the fluid portion, and fibrin in the solid parts. Chemical observation had now demonstrated to Professor Andral the fallacy of this opinion. The fluid contained no albumen whatever, and the white grains floating in the liquid were not constituted by fibrin. Examined with the microscope, these particles presented the appearance of pus globules; but still they were not purulent. In the blood, albumen was found in its natural proportions. The learned professor concluded by stating as his opinion that the choleric matter consisted only of a modified mucous secretion.

ACADEMY OF MEDICINE.

Meetings of Aug. 7 and 10; M. BEGIN in the Chair.

VACCINATION.—An official report on this subject was read by M. Desportes; a long debate ensued, which occupied both the meetings; it was decided that in the majority of each circumscription, a register of vaccinations should be kept with as much regularity as that containing the entries of births and deaths. The reporter had further proposed that the authorities should recommend, in cases of pressing danger, during an epidemic of smallpox, inoculation of variolic pus, but this part of the report was not adopted by the academy.

Meeting adjourned at five o'clock.

MERCURIAL TREATMENT IN TYPHOID FEVER, BY M. SERRES.—M. Serres begins by stating that, in his opinion, typhoid fever consists in an exanthematic affection of the intestines. The febrile excitement, the diarrhoea, abdominal symptoms, and cerebral manifestations are entirely governed in their progress and intensity by the intestinal eruption. In this respect M. Serres thinks that typhoid fever can be most properly compared with smallpox, in which Sydenham has shown that the violence of the malady is always proportioned to the confidence or mildness of the cutaneous eruption. The professor, therefore, concludes that, by keeping the intestinal disease under control in typhoid fever, the general reaction, its consequence, will be thereby prevented from attaining any dangerous height; and no medicine seems to M. Serres so well calculated to produce this result as mercury. Every second day M. Serres prescribes the following pills:—*R. Hydrarg. sulphureti cum sulphure, gr. xvij.; tragacanthæ, gr. x.; syrup q.s. fiat massa in pilul. iv. dividenda.* Every morning inunctions with ʒij. of mercurial ointment are made upon the abdomen. The treatment is suspended when incipient stomatitis is noticed. Under the influence of mercury, diarrhoea is gradually arrested, the tympanitis reduced or prevented, and, although the average

duration of the malady is not diminished, still its violence is much abated.

PHYSIOLOGY.—USE OF THE SALIVARY SECRETION, BY M. BERNARD.—The recent researches of Mialke and others tended to show that saliva contains a ferment capable of changing starch into sugar. The experiments upon which was founded this opinion consisted in chemical researches on the fluid escaping, during a given time, from the mouths of animals. M. Bernard derives from a new series of experiments a contrary opinion. Instead of merely collecting the buccal secretions, he took the saliva from the glands themselves, and states that in this unaltered and pure condition that fluid is incapable of causing saccharine fermentation in starch. Pursuing his experiments, M. Bernard separated from the mouth of a dead horse several shreds of the mucous membrane, and found that, after prolonged desiccation, they still retained the power of transforming starch into sugar. It is, therefore, the mucous membrane, and not the saliva itself, which causes this change in amylaceous substances. The function of saliva is then simply, according to M. Bernard, to moisten the alimentary bolus, and to connect its various parts into a homogeneous paste.

HOPITAL SAINT LOUIS.

CLINICAL LECTURE, BY M. CAZENAVE.—IMPETIGO.

This is a non-contagious disease characterized by the eruption of small pyodermic pustules, generally very confluent, and which, on drying, leave thick, rough, and yellowish crusts. The seat of the disease is in the lymphatic apparatus of the skin. It is often attended on its first appearance by loss of appetite, headache, and slight intestinal disturbance; small red patches soon make their appearance; on these the pustules form, and, desiccating in the space of three or four days, form a crust which has been compared to dried honey; the scabs fall off after a short time, and are replaced by others, unless the eruption is arrested in its progress: it is in this form that impetigo is most generally met with in childhood, and it may persist with the same characters for a considerable length of time. In a chronic form, it attacks all ages, and more particularly persons of a lymphatic temperament. One of the most severe varieties is met with in the aged, when an entire limb is often occupied; the skin thickens, motions become painful and difficult; oedema makes its appearance; the nails fall off, and fresh crusts rapidly replace those which drop away. This is Willan's "impetigo scabida."

We recognise four forms of impetigo, viz.—1, *I. sparsa*, chiefly observed on the limbs and about the joints; 2, *I. figurata*, principally occupies the face, and affects usually a circular or oval form; 3, *I. granulata*, invades the scalp, and betrays its presence by the eruption of yellowish pustules perforated by a hair, and are often followed by temporary baldness; 4, *I. larvalis*, common in first childhood, often covers the face like a mask, and has been subdivided into porrigo granulata and porrigo larvalis, which Willan believed to be constituted by a peculiar sort of pustule, viz., *achores*.

Impetigo is observed in all seasons and at all ages; lymphatic subjects are specially predisposed to it; but in general the eruption is attended with no sort of danger, although its appearance generally creates much unnecessary uneasiness in families.

From *ecthyma*, impetigo will be distinguished by the smaller size of its pustules and the brighter colour of the scabs; *ecthyma* chiefly attacks the lower extremities. *Sycosis* occupies generally the lips or chin; its scab is drier than that of impetigo, and covers a tubercular induration of the subjacent skin. The presence of the general symptoms in *variola* will prevent the possibility of any confusion. In *eczema impetiginodes* the scab is thinner, lamellated, and greyish.

With regard to treatment, we recommend in the acute stage, acidulated drinks, a few baths, laxative medicines, and even when the disease is very intense general or local bloodletting. In-

ternally we have tried the hydriodate of potash, but without benefit; we prefer cod-liver oil, sulphur, and bitter medicines; we particularly applaud ourselves upon the results yielded by the crystallized muriate of lime, which we exhibit in the following manner:—*R. Calcii chloridi (crystallizati), ʒss.; aquæ, ʒxij. ft. mistura, capiat cochlearia, 3 amplia in die.* Ointments of all sorts are more injurious than useful; we have seen some rebellious cases yield to vapour-baths and to Pearson's arsenical solution (liquor sodæ arsenitis).

DISLOCATION OF THE FEMUR UPWARDS AND FORWARDS ON THE PUBES.—On Aug. 5, 1846, a workman was struck on the outer side of the right thigh by a bag of corn, which dropped from a height of thirty feet. When the patient was raised he could not use his right leg, and complained of pain in his hip and knee. Three hours after the accident Dr. Aubry was called. The wounded man was lying on his back, the right leg being one inch shorter than the left, everted, and lying on its outer aspect; the leg was slightly bent, and the trochanter less distinct than usual; immediately outwards of the middle of the inguinal fold was seen a round, hard tumour, formed by the head of the femur. For the purpose of reducing the dislocation, the patient was laid upon a table, and the pelvis being fixed by two assistants, the femur was bent with some effort at right angles with the body, at the same time that it was turned inwards. At the end of one minute and a half the bone returned to the cotyloid cavity.

—D. M'CARTHY, D.M.P.

Malignant Bilious Pneumonia.—This disease has prevailed very extensively in Georgia and South Carolina, U.S., during the last two years, and has been attended with an extraordinary degree of mortality. The disease called the "black tongue," which prevailed at one time to a great extent in the north-western extremity of Hall county, is thought by Dr. J. Rivers, who communicated the account of the bilious pneumonia to "The Philadelphia Medical Examiner," to be another form of this disease. The diagnostic symptoms are rigors, but never a shaking chill; coldness of the body and extremities; pain in the forehead, generally an inch or two above the orbits of one of the eyes, most commonly over the left eye; severe pain in the chest, usually on the right side; pain in the region of the liver and in the abdomen. As the malady advances in its inflammatory course the tongue thickens and expands laterally. In the outset of the disorder the pain is metastatic, sometimes moving from the head to either lung, usually the right one, frequently to the superior lobe of the lung, then its lower part adjacent to the diaphragm, then to the liver, and finally the abdomen, in the region of the large intestines. It is not uncommon for this moving pain to lessen in intensity in one part of the body and to increase in a corresponding ratio in another organ at a considerable distance. Sometimes the eye contracts and shrinks, and is turned towards its inner canthus, and vision becomes so impaired that objects appear double, the pain being much more acute in the region of the lungs and liver than in the head. In two instances there was noticed numbness of the extremities; in all there was serous congestion, and generally a corresponding increase of action in the arteries. In two instances abscesses formed, in the early stages, in the soft parts of the lower jaw. The treatment of this disease in its metastatic state yields to stimulants and diaphoretic ptisans. Brandy-and-water was found to be an excellent remedy in the incipient stages, during the metastasis of the pain. A tea made of the eupatorium perfoliatum, sufficiently strong to act as an emetic or purgative for a short time, when diluted and given as a diaphoretic, is also a valuable remedy in the first stages of the affection. But, whenever the disease becomes settled in any organ of the body, the antiphlogistic treatment is the best; and in no cases where expectoration had not taken place were stimulants, opiates, or animal diet given. Far-

naceous diet is the most suitable before expectoration has become free.

New Mode of Operating for the Cure of Vesico-Vaginal Fistula.—Dr. Pancoast, professor of anatomy in Jefferson Medical College, U.S., has operated upon two patients, in one of which was a complete destruction of a cross section of the whole urethral structure at its junction with the neck of the bladder; in the other there was an elongated orifice in the *bas fond* of the bladder, which would more than admit the end of the finger. The peculiarity of the operation consists virtually in attaching the two sides of the normal opening firmly together, on the principle of the tongue and groove, so as to get four raw surfaces in contact, and thus increase the probabilities of union by first intention. For this purpose it is necessary that the margins of the fistula should have considerable thickness; and, when not found in this state, they are to be thickened by repeated applications of lunar caustic or, better still, of the actual cautery. Having exposed the fistulous orifice as thoroughly as possible with a Charrière's speculum, from which the sliding blade has been removed, an assistant drawing the vestibulum well up towards the front of the pubes, the most posterior margin of the fistula is split to the depth of half an inch with a sharp-pointed sabre-shaped bistoury. The edges of the other lip of the fistula are then pared off so as to bring it into a wedge shape, first reverting it as much as possible with a small blunt hook, and trimming off the mucous membrane on the side next the bladder with the curved scissors or scalpel, and then detaching, in like manner, the vaginal mucous membrane, to the breadth of three-quarters of an inch, along the whole extent of the lip. This is a very difficult but most important part of the process; and great care should be taken to obtain a sufficient extent of raw surface at the two angles of the fissure, when the lips will rest merely in apposition. The bleeding being checked by astringent applications, the raw wedge or tongue, into which one of the lips of the fistula has been converted, is to be inserted into the groove which has been cut in the other, and held in close connection by means of suture threads, passed with short, sharp, curved needles, held in artery forceps, with handles made of twice the ordinary length. The sutures are left until they become loose. A gum catheter should be kept in the bladder to prevent the accumulation of urine. To keep down inflammation, a bladder of cold water should be applied for thirty-six hours to the vulva. On the second day after the operation, sulph. of zinc in solution must be frequently injected, to give tone to the parts. On the third or fourth day a solution of lunar caustic must be applied to the line of union with a camel's hair pencil, twice in twenty-four hours, the strength of the solution being gradually increased.

Traumatic Tetanus Successfully Treated.—Dr. O. H. Costill, of Frankfort, Pennsylvania, attended a coloured woman who, two days previously to the visit, had been wounded with a carpet tack in the right foot. It was withdrawn without any inconvenience being felt till the evening following, when she complained of pain in the foot and stiffness in the leg and back. The next morning, when Dr. Costill saw her, the arms, legs, and whole frame were perfectly rigid. Eyelids drawn down so tightly as scarcely to be lifted, and her jaws firmly set. The surface of the body being cold, she was placed in a warm bed, and hot applications directed to the feet. After some time the spasm subsided. The anterior part of the sole of the foot was now found to be so tender that the patient could scarcely bear it touched, but no point where the nail had entered could now be discovered. The pain extended up the leg and back to the neck and jaws, and there was stiffness about the root of the tongue. A rye poultice to be applied to the foot, and a mixture of castor oil and turpentine to be given every hour and a half till the bowels should be freely moved. At twelve o'clock the medicine had not operated, and she had had one severe spasm. During the afternoon she became

worse, and had more than a dozen spasms. Her breathing was difficult, as if choking; jaws set, and foam proceeding from the mouth. The body was bent in a bow shape, resting on the occiput and heels (opisthotonos). There was excessive tenderness on the anterior part of the sole, about the size of a crownpiece. Within this space two incisions were made, crossing each other at right angles, into which lint saturated with spirits of turpentine was inserted, and the rye poultice reapplied. A pill containing two grains of opium and two of calomel to be taken every hour. At nine in the evening she had taken two pills, and had had no spasms. One pill to be taken every hour through the night. By nine the next morning she had taken four pills and had no spasms. In the evening of the same day had two, but not severe. A solution of caustic potash was to be applied along the course of the spine. Next morning she was sick and vomited a light green fluid. The pills to be continued, and an enema to be given, as the bowels had not been relieved. The bowels from this were freely relieved, the mouth shortly became sore, and, although she was distressed with occasional sickness, she began to sleep. The wound continued sore for a few days, and healed without suppuration. The spasms did not return after a free use of the opium and calomel.

Congenital Obstruction of the Colon in an Infant.—The child was a male, and lived three days from its birth. It was at first cheerful and took the breast, but gradually became languid, and sunk without evident cause, except the want of a discharge per anum. The post mortem was conducted by Dr. James Bryan. The abdomen was very tumid, and on making an incision through the integuments a large quantity of fetid gas escaped; the bladder was healthy and contained a little urine; the urachus was attached to the umbilicus and bladder; the peritoneum in every direction was engorged with dark-coloured blood, and the circulatory arcades of the mesocolon with the small vessels of the colon were filled with blood, and easily seen when the intestine was held between the eye and the light. The greater part of the hypogastric region was filled by a tumour about four inches in diameter. On opening the colon above this tumour (which proved to be situated in the sigmoid flexure of the colon), large quantities of meconium and fecal matter were discharged. The peritoneum when divided was found to cover a smooth surface of the tumour; this surface proved to be the outer coat of the intestine, which was very much distended, and contained the tumour in the form of coagulated blood, as black as pitch. The descending colon was distinctly traced into the covering, and was found to adhere to the margin of the pelvis, and to be entirely imperforate in the direction of the rectum. The anus was in a natural condition; a probe would pass without difficulty up the rectum to the obstruction. The explanation of this case would appear to be, that a rupture of some of the vessels of the sigmoid flexure of the colon took place during uterine life. A gradual discharge of blood into the intestine and between its coats supervened, producing pressure on the surrounding parts, and in this way causing adhesions to such an extent as to close the passage of the blood towards the rectum.

Gunshot Wounds in the different Assaults by the United States Armies on Monterey.—Dr. N. S. Jarvis, United States army, records ten cases of individuals wounded in battle. In the first, a corporal was struck by a musket-ball on the anterior and central portion of the os frontis, destroying it for a distance of two inches. Considerable portions of the brain issued from the wound, and, notwithstanding the severity of the case, the patient appeared to suffer little or no inconvenience until the third day, when coma supervened, followed by delirium, and he died.—A private received a wound in the right eye, supposed to be from a fragment of stone broken from the wall by a cannon-shot, and which struck the man with such force as to knock him down. Two or three hours after the injury the

eyelids were so much swollen as to render it very difficult to ascertain the condition of the eye. A hard, sharp substance, however, was felt near the inner canthus on the application of the finger. This was immediately extracted with a common forceps, and found to be a fragment of grape three quarters of an inch in length, and half an inch in width at the centre, of an oblong shape. The eyeball was uninjured, the fragment having passed between it and the inner canthus, penetrating to the posterior wall of the orbit, destroying the lachrymal sack, the os unguis, and wing of the sphenoid bone. Considerable inflammation and suppuration followed, and, though the wound healed, the pupil remained dilated, and the vision destroyed.—Another received a musket-ball near the angle of the inferior maxilla on the right side, fracturing the bone, passing directly through the tongue and the corresponding portion of the bone on the opposite side. The tongue was completely separated at its base, hanging only by a few muscular fibres. The patient died very speedily from excessive hemorrhage.—A major of infantry received a wound from an *escopete ball* (a ball one-third larger than that carried by a musket), directly in the centre of the upper lip. It passed obliquely backwards to the left, tearing away the bony palate, completely destroying the upper maxilla and malar bones of that side, and, fracturing the condyle of the inferior maxilla, passed out behind the ear near the mastoid process. The velum palati was completely separated from its superior connection, and rested on the tongue. The whole of the alveolar process, together with the teeth of the left side, was carried away. To enable him to articulate as well as swallow, the pendulous palate was fastened by a stitch, and afterwards by a ligature placed around the remaining incisor tooth. It was afterwards more completely secured by a strong ligature passed through it in two places, the ends being brought together, and by means of a probe carried up through the nostril, and fastened with adhesive plaster to the forehead. Intense inflammation followed, involving the whole side of the head, and during several days pieces of bone were constantly separated and discharged. Little recuperative efforts were made by nature in consequence, perhaps, of an attack of intermittent fever, and the patient ultimately died.—A private of dragoons was struck by a copper grape-shot at the same point as in the preceding case, passing obliquely backwards and downwards, wounding the tongue, and fracturing the lower jaw on the left side near its angle, then, coursing along the neck beneath the integuments and muscles, lodged near the left sterno-cleido mastoid muscle into the clavicle, where it was cut out. Fragments of bone came away, and considerable inflammation with difficulty of swallowing followed, but the wound progressed favourably, and, notwithstanding the size of the shot and destruction of the parts, is at the present time nearly healed. His head is considerably drawn down, and a rigidity of the jaw, with inability to speak, remains.—A lieutenant of infantry was wounded in three places at the same time. The most severe wound was one in which the ball, striking the upper and anterior portion of the thigh, entered the pelvis, wounding the fundus of the bladder, and passed out at the sacro-sciatic notch. The femoral vessels in the course of the ball escaped being wounded. The urine, passing freely through the wound, produced considerable infiltration and inflammation of the cellular tissue of the thigh. By changing his position so as to be on the left side, and introducing a catheter, which was constantly maintained in the bladder, no more urine escaped through the wound, and the inflammation rapidly subsided. The usual separation of the parts destroyed in the course of the ball took place, succeeded by a healthy suppuration, but he expired on the twenty-second day after being wounded.

Number and Results of the Larger Amputations after the Assaults on Monterey.—The total number

in the three divisions of the American army was twenty-eight, viz., ten in the first division, four in the second, and fourteen in the third or volunteer division. Twenty were performed in the field, or on the following morning in the camp; the remaining eight at subsequent periods, varying from five to twenty days. Twelve of the number, including two of those taken prisoners and operated upon by the Mexican surgeons, proved fatal, and the remaining sixteen have nearly or quite recovered. This average of mortality was not confined to the wounded of the United States army. Dr. Hidalgo, surgeon in charge of the Mexican Military Hospital, reports that, of thirteen operations performed there, six had proved unsuccessful. The wounded of the United States army were subjected to repeated removals from the field to the camp, and from the latter place to the town; and in two cases this was evidently productive of a fatal termination. Moreover, the moment a limb was amputated, hosts of flies would light upon the stump, there speedily depositing their eggs, for when it became necessary to dress the stump, myriads of maggots were often found buried in it, which could be expelled with great difficulty—rendering it necessary, in some instances, to reopen the flap for their complete extermination. Erysipelatous inflammation frequently occurred of the integuments covering the stump, which generally set in two or three days after the operation, producing sloughing, which, if not causing death, rendered a second amputation necessary.

Penetrating Wound of the Thorax, with Protrusion of a Portion of the Lung.—Dr. Geo. Johnson, surgeon, United States army, relates the case of a man who received a wound in his chest, about an inch below the left nipple, from a large bowie knife. On examination a piece of lung, two inches and a half or three inches in length, was found protruding from the wound. The knife had passed between the ribs downwards and outwards. It was at least three inches in length. The wounded portion of the lung was introduced within the thorax, and the external wound closed with the interrupted suture. The man was kept under the strictest antiphlogistic treatment, and in twelve or fifteen days after he was convalescent. The knife with which the wound was given was two inches wide, and must have penetrated the lung four inches.

Case of Doubtful Sex.—Dr. Wm. James Barry, of Hartford, Connecticut, was requested, in March, 1843, to examine Levi Sugdam, twenty-three years of age, a native of Salisbury, Connecticut. The following are the appearances which were presented:—The mons veneris was found covered in the usual way; an imperforate penis, subject to erections, and about two inches and a half in length, with corresponding dimensions; the dorsum of the penis connected by cuticle and cellular membrane to the pubis, leaving about one inch and a half free, or not bound up, and towards the pubic region. This penis has a well-formed glans, with a depression in the usual place of the meatus; a well-defined prepuce, with foramen, &c. The scrotum not fully developed, about half the usual size, and not pendulous. In the scrotum on the right side was a testicle of the size of a common filbert, with spermatic cord attached. In the perineum, at the root of the corpora cavernosa, an opening through which micturition was performed, large enough to admit the introduction of an ordinary-sized catheter. It was found upon inquiry that this being of a doubtful gender menstruated as regularly, but not as profusely, as most women. He is five feet two inches in height, light-coloured hair, fair complexion, with a beardless chin, and decidedly of a sanguineous temperament; narrow shoulders, and broad hips; well-developed mammae, with nipples and areola. On passing a female catheter into the opening through which micturition was performed, and through which the periodical bloody discharge proceeded, instead of traversing a canal, and drawing off urine, the catheter appeared to enter immediately a passage similar to the vagina, three or four inches in depth, and in

which there was considerable play of the instrument. He stated that he had amorous desires, and that at such times his inclination was for the male sex. It was ascertained that, the second day after he was born, the accoucheur made, with an instrument, the opening through which he has ever since performed micturition. Notwithstanding his doubtful gender, he is admitted a freeman and citizen of the United States.

Death by Strychnine.—Dr. Warner, a medical practitioner, of Montpelier, U.S., having been accustomed to take sulphate of morphia for an inordinate action of the heart, a sequence of inflammation of the chest, called at an apothecary's shop for some, when he was served with strychnine by mistake. A portion of this was taken without unwrapping the bottle, which was found subsequently to be properly labelled "strychnine." He was immediately seized with constriction of the throat and tightness of the chest, with rigidity of the muscles on attempting to move. Dr. Horton was in attendance immediately after the accident, and found the patient on the bed in a complete tetanic convulsion; his head somewhat drawn back; his countenance livid, with some fatty matter issuing from his mouth, and moaning at intervals. The palpebre were constantly in motion. The first paroxysm lasted about five minutes, which was succeeded by a perfect calm. During this interval it was somewhat difficult for him to articulate with distinctness. He made several attempts to vomit by exciting the fauces with his finger. After five minutes another paroxysm commenced by a little starting and stiffening of the extremities, and immediately the whole body was thrown into a tetanic paroxysm, in appearance like the first, and lasted two or three minutes, when death ended the struggle. From the information obtained, the patient could not have lived more than from fourteen to twenty minutes after taking the poison, which was, probably, from one-fourth to half a grain. The remedies used were, dashing cold water on the face, head, and neck; using the most powerful friction on the extremities; and, during the interval of calmness, administering an emetic of sulphate of copper, with ipecacuanha. Ground mustard and warm water were also freely used, to all of which the patient submitted, appearing very grateful for the efforts made to relieve him. The means used were without any apparent effects. In a medical point of view, the case is one of considerable interest, as it clearly manifests the true and energetic character of this medicinal agent. In the suddenness of its effects, and in the quickness of the fatality, the case has scarcely any precedent.

Nitrate of Silver a Remedy for Croup.—Dr. Bateman, United States, relates two cases of croup, in which, having used powerful emetics with mercury without any apparent benefit, he cauterized the larynx with a solution of nitrate of silver (a dram to the ounce). The application was somewhat difficult, and the dyspnoea very great. A quantity of thick tenacious substance was brought away by the sponge, and more by the vomiting which followed. After an interval of ten minutes a second application of the solution was made, which brought away a still larger quantity of membranous matter on the sponge than before, and a much more copious discharge accompanied the vomiting caused by the application. The disease seemed to be arrested, the breathing became better, and the barking sound was heard only at intervals. A third application of the caustic was made five hours and a half after the first application, which brought, as before, some thick tenacious matter, differing from the first, in being of a yellow colour. The vomiting which followed threw off a large quantity of the same yellow-coloured, thick substance, so tough that it could be raised from the bowl by the fingers. After this no further treatment was required.

Poisoning from Swallowing Percussion Caps.—Dr. T. W. Foster, of Keene, Jessamin county, Kentucky, was called to assist an infant, fourteen months old, who, while playing with a box of percussion caps, swallowed some of them.

When visited the patient appeared to be sinking fast. The eyes were hollow and glazed; great heat in the epigastric region, and coldness of the extremities; there had been eight or nine discharges from the bowels in an hour. There had been free emesis produced by some domestic remedy, and the vomiting was promoted by administering ipecacuanha and large quantities of warm water, of which the patient eagerly drank. The discharges becoming debilitating, an injection of eight drops of laudanum, suspended in starch mucilage, was administered, and a large dose of calcined magnesia given. An alkaline purgative was selected, for the purpose of neutralizing any acid which might be found in the stomach or intestines, and thus prevent any chemical change in the copper. In the course of an hour the child became composed, fell into a slumber, though it had previously suffered excruciating pain. The next day four caps were found in the fecal matter, devoid of powder, and the child shortly after regained its wonted health.

Nervous Affections.—M. Pallas states, that as terrestrial electricity is the cause of many nervous affections, he has cured numerous patients thus afflicted by adapting to the bedsteads on which they sleep glass feet, and removing them about eighteen inches from the walls of the apartment.

REVIEWS.

The Microscopic Anatomy of the Human Body, in Health and Disease. Illustrated with numerous Drawings in Colour. By ARTHUR HILL HASSALL, M.R.C.S.E., &c. Part X. London: S. Highley, 1847.

Mr. Hassall deserves well of the profession for the punctuality with which the numbers of his excellent work issue from the press, the way in which it is got up, and the scientific information it gives in comparatively a small compass. We have shown our estimation of this valuable addition to our professional literature by the extracts which we have occasionally made in that department of the *Medical Times* devoted to the progress of science. The tenth part, which has just issued from the press, well sustains the high character which the preceding numbers have acquired, the various articles being well written, and the coloured lithographic plates neatly executed. Three articles and four plates constitute the present number—the former treating of the cellular or fibrous tissue, muscle, and nerve, the latter of the structure and development of bone. On "cadaveric rigidity," which sometimes presents remarkable phenomena, we have the following remarks, under the section of muscular contraction:—

"The stiffening of the body, which occurs after death, known by the terms, 'rigor mortis,' 'cadaveric rigidity,' is due to muscular contraction. This rigidity usually comes on a few hours after death, and, after continuing for a variable time, not exceeding six or seven days, again disappears. There is much variety, however, in the exact periods of the advent and departure of the rigidity: it has been observed to come on latest, attain its greatest intensity, and to last longest in the bodies of robust persons, who have either died of short and acute diseases, or who have suffered a violent death. On the contrary, it has been remarked to set in soonest and to disappear earliest in persons of feeble constitution, and those who have died of a lingering and exhausting malady. The immediate cause of cadaveric rigidity has never yet been satisfactorily explained. Some have supposed that it depends upon the coagulation of the blood in the capillaries—an hypothesis scarcely tenable; others, with more reason, conceive that it proceeds from the solidification of the fibrine of which muscle is chiefly constituted—that it is, in fact, a phenomenon precisely analogous to the coagulation of the fibrine of the blood. An explanation, differing from both of the former, has suggested itself to my mind. I conceive that muscular

contraction may possibly be brought about by the stimulus of the thinner and more watery parts of the blood, &c., acting on the still irritable muscular fibre, and which are known to escape from their containing vessels very shortly after the extinction of life. Of this passage of fluid through the walls of its receptacle we have a familiar instance in the case of the gall-bladder and its contents."

Popular Cyclopædia of Natural Science. By W. B. CARPENTER, M.D., F.R.S., In Parts.

Perhaps few men could be found in the present day better qualified for discoursing popularly on natural history than the author of the work before us. Possessed of untiring industry, that for years past has been devoted to the gathering and distributing of information on all subjects connected with human and comparative physiology; and possessing a remarkable facility in arranging and condensing matters of fact, and giving utterance to them in clear and concise language, we feel assured that, as a collector of natural-history truths, in a cyclopædial form, he will not only add to his own reputation, but considerably facilitate an acquisition with the fascinating science he has undertaken to teach. We wish him every success in his laborious undertaking. The work is neatly and very cheaply issued, and we have no doubt it will enjoy, as it deserves, an extensive circulation.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any *swoman* or *Bookseller*, or it will be sent direct by post from the *Office of the Medical Times* to *Subscribers* sending by a *Post-office order*, directed *James Angerstein Currae*, or an order on some party in town, *One Guinea IN ADVANCE*, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

Scrutator.—The instrument is a steel sound, so shaped as to combine the advantages of the wedge and the lever; it is said, that "by giving an obtuse edge to the cone of the instrument, which by the flattening of the two sides is nearly triangular, less resistance is made to its passage through the stricture, and a dilatation of the part is far more readily effected than by the mere conical sound, and more especially in the denser kind of stricture, the removal of which cannot be effected without great perseverance in the ordinary and tedious process of treatment by the common bougie."

A *Licentiate* of the *London College of Physicians*.—It does not come within our province to touch upon the subject mentioned; the paper is, therefore, at the disposal of our correspondent, with thanks for the offer.

A *Member* of the *National Institute*, *Rotherhithe*.—The meeting was extensively made known, and it must have been by some oversight that our correspondent received no notice of it. There was a good attendance, and a united disposition to maintain the *Institute* in all its efficiency.

A *Sufferer from Illegal Practices*.—We know of no better means "to stir up the *Apothecaries' Society* from their slumbers" than by teasing them with letters, or by personal applications to their officers. Our correspondent bitterly complains of the neglect which he has experienced from the *Society* in reference to an application he made concerning an *illegal practitioner* in his neighbourhood. The penal clause seems to be just now rather a troublesome piece of property.

Mr. T. Ewins.—The representation should be first made to the *Council of the College of Surgeons*, and, if no notice be taken, to publish immediately.

Phil. Jobson.—We think the subject of rather too serious a nature to be treated lightly. Draw out the facts in a plain unvarnished narrative, authenticate the communication, and it shall appear in our columns.

Dr. T. Macpherson.—A private letter shall be sent in the course of a few days.

A *Student*.—The questions are so many that we can neither spare time nor paper to answer them all. If our correspondent will be a little moderate we shall be able to accommodate him.

M.D.—To speak of Oxford as a respectable medical school is, in our estimation, little better than folly. Its degrees may be held in high estimation, but its capabilities of imparting anything like a respectable medical education are very few.

A *Young Surgeon*, *Queen-street, City*.—No engagements should be undertaken without a clear understanding in reference to salary. The duties of the surgeon on board such a ship would be laborious and responsible, and a young man would be very silly to undertake them without some consideration in addition to a free passage.

A *Candidate for Parochial Honours*.—Our correspondent is certainly not serious. He will, perhaps, find by experience that the honours for which he longs may be very empty ones. The double qualification is necessary to bring them within reach.

A *Member of the National Institute*.—We are aware that the condition of members of the class to which our correspondent belongs is very wretched, and we know not how it is at present to be improved.

A *Provincial Surgeon*.—The Government measure of sanitary reform did not pass into a law during the last parliamentary session.

A *Member and Licentiate* wishes to know how the case of *Michael Sweetman* has been disposed of? Apply to the clerk of the *Apothecaries' Society*.

Mr. R. Reid, Bodle, Liverpool.—The only alternative that we know of, under the circumstances, is to adopt the plan mentioned in the last clause of the note.

Mr. G. C. Churchill, Manchester.—We may very shortly be able to publish the lectures.

***, *Atherstone*, is thanked for the communication.

Mr. Jas. Rolph, Paradise-row, Bethnal-green-road, wishes us to correct a mistake which appeared in the list of gentlemen who passed their examination at the *College*, August 6, 1847. The name was spelt *Ralph*, instead of *Rolph*.

Mr. Corfe, Middlesex Hospital, shall have his request attended to.

Mr. Thos. Buchanan, Hull.—The "Synoptical Table" came safely to our office, and at an early opportunity will be noticed.

Medicus.—Yes.

Mr. Alfred Ebsworth, Bulwell, Notts.—The letter has been received.

A *Correspondent* wishes to be informed what medical man of any authority was the first to notice the appearance of smallpox in Great Britain.

Mr. Edward Fielding Palmer, Tamworth.—The communication has been received.

Mr. Edward L. Falloon, Liverpool.—We will insert the case, and return the drawings as requested.

S. H., a *Subscriber*.—The difficulties are almost insurmountable, and, if our correspondent has had brilliant visions of the future, he will be assuredly disappointed. The church offers greater encouragements to talented young men, who are poor, than the medical profession.

C. C.—We can only recommend economy during the enjoyment of health. We know of no institutions which would render permanent help to such medical assistants.

R. H. W.—We can only publish authenticated communications relating to the *Putney inquest*. Our correspondent's wishes can only be gratified by his allowing us to use his name.

Aner.—We are unable to answer the question. **Mr. J. H. Williams.**—Fair remuneration for such professional services as are mentioned will no doubt be granted at the quarter sessions.

In consequence of announced legal proceedings against the Editor of the "Pharmaceutical Journal," Mr. Farmer wishes us not to publish the letter which we announced from him last week, on the subject of the late inquest at Putney.

Letters and communications have also been received from *Mr. Allison, East Relford*; *Mr. E. Daniell, Newport-Pagnell*; *Mr. Charles W. Webb, Imprest*; *Mr. Edward Fielding Palmer, Tamworth*; *Mr. Alfred Ebsworth, Bulwell, Notts*; *Mr. T. Buchanan, Hull*; *Mr. Corfe, Middlesex Hospital*;

Mr. James Rolph, Paradise-row, Bethnal-green; *Mr. G. C. Churchill, Manchester*; ****, Atherstone*; *Mr. R. Reid, Bodle, Liverpool*; *A Member and Licentiate*; *Mr. J. H. Williams, Aner*; *R. H. W.*; *A Provincial Surgeon*; *An Assistant*; *A Candidate for Parochial Honours*; *A Young Surgeon, Queen-street, City*; *M.D.*; *A Student*; *Dr. Thomas Macpherson*; *Phil. Jobson*; *Mr. T. Ewins*; *A Sufferer from Illegal Practices*; *A Member of the National Institute, Rotherhithe*; *A Licentiate of the London College of Physicians*; *Scrutator*; *Mr. Edward Falloon, Liverpool*; *C. C.*; *S. H.*, a *Subscriber*.

THE MEDICAL TIMES.

SATURDAY, AUGUST 21, 1847.

FLOATING PESTHOUSES.—FRIGHTFUL MORTALITY AMONGST EMIGRANTS.

Quam multa in sylvis autumni frigore primo
Lapae cadunt folia, aut ad terram gurgite ab alto
Quam multæ glomiesantur aves, ubi frigidus annus
Trans pontum fugat, et terribis lummittit apricis.
VIRG., *Æneid*, lib. 8.

THE condition of many of the vessels which are sent across the Atlantic crammed with emigrants is such as to reflect the greatest disgrace upon those merchants whose property they are, and by whom they are sent out for the purpose of putting money into their pockets, and upon the Government for permitting such craft to leave our shores crowded with human beings. Wealth is acknowledged to be omnipotent amongst us, and the despotism which it exercises has lowered our national character in the estimation of all the civilized nations of the world, because it has been guilty of perpetrating the most outrageous deeds upon those who have been too weak to resist its aggressions. At the present moment the health and energies of the people are suffering from obstructions which monopoly has placed in the way of social improvements, and multitudes of human beings are daily immolated upon the altars of a bloody Moloch, who derides the sufferings of its victims when the coffers of its treasury are replenished at their expense. Philanthropists have been bearded by this tyrant, and their best efforts have been counteracted by his unholy exertions, so that in the nineteenth century we suffer from abuses which would disgrace barbarous countries. In the midst of populous cities graveyards and sewers, filthy hovels and stagnant ditches, are suffered unmolested to send forth their pestiferous exhalations to slay their tens of thousands, while many of our ships, from causes which could be removed, are no better than floating pesthouses conveying to other climes the most deadly diseases.

Public attention is beginning to be directed to that part of the mercantile navy which is employed in conveying emigrants to different parts of the globe, as at the present time a fever is raging amongst those unfortunate beings who have voluntarily exiled themselves from their native country to settle either in the United States or Canada. At *Grosse Island* the quarantine hospitals contain two thousand patients, and the institutions for the reception of the sick at *Quebec* are so full that no more can be accommodated. Here, however, the great bulk of the emigrants do not remain, as they are conveyed by steamers on to *Montreal*, and to the western districts of the colony; and it is in these places the extent and power of the disease are so fearfully displayed.

It was early in May that the first vessel arrived with the fever amongst its passengers, and since then scarcely a day has passed without fresh cargoes of human creatures being landed, suffering more or less from the malady which they contracted on board ship. The mortality has been so great that at least one-eighth of the total number, who left their own country with the hope of bettering their condition, either found a premature grave in the waters of the Atlantic or on the shores of the Western Continent. It appears from the statement of some of the daily papers that no less than 57,000 persons had arrived in the river St. Lawrence, and that the deaths from typhus fever amounted to about 7000. They are as follows:—

Died at sea	2216
Died after arrival, but before landing	1011
Died at (Grosse Island (up to 17th of July) 1201	
Died in the Marine Hospital, in Quebec ..	150
Died at Montreal	1400
Died at various places in the provinces.	800

Total

Here is a mortality truly awful to contemplate, produced by a single disease, and which calls for a prompt and searching investigation, in order that its origin may be discovered and its ravages staid. It might have been anticipated that, as the emigrants are composed principally of the inhabitants of the "Sister Isle," where typhus has been prevalent, that there would be amongst them an increased amount of disease, and that, from the wretched condition of the quarantine establishments in Canada, there would be more than an average mortality amongst the fever patients. Yet we are to look for other causes than the Irish epidemic and colonial supineness for the vast increase of disease and death amongst the emigrants. The *Morning Chronicle* complains bitterly of the station at Grosse Island, which, it says, "was kept up rather as a comfortable farm for the superintending surgeon, than as the sanitary gateway of England's most valued colony. The dead, the dying, and the sick arrived; the buildings in the island, mere outhouses at the best, were rapidly filled; and then the luckless wretches, for whom no room could be found to die under a roof, were laid on the grass in tents, with the rotten beds they had brought from home; four hundred are thus provided for; and, as for some days past much heavy rain has fallen, their present state must be one of the most fearful misery. There are but eight surgeons to attend to two thousand patients, and it is said that many of them do not possess the qualifications which so responsible a position requires." We leave for the present the Grosse Island establishment, with its sheds, surgeons, and sick, to the tender mercies of the *Chronicle's* correspondent, in order that we may more especially attend to the merchant carriers and their craft.

Few, perhaps, are aware of the wretched hulks which are oftentimes "put in commission" to convey voluntary transports from the shores of Great Britain and Ireland to those of America. Every trick is resorted to to entrap passengers. Paint, putty, oakum, and pitch are liberally employed in all directions, in order that all defects might be so nicely covered as to escape observation. Chloride of lime, and other disinfecting agents, are used, while in port, to keep down the stench produced by the bilge-water and other impurities of the vessel, which would be anything but attractive to those seeking berths.

These vessels, however, contain within them the latent elements of malignant disease, when, from any cause, individuals are so weakened in constitution as to render them susceptible of its influence. Some ships are scarcely seaworthy; and the steerage is not unfrequently so crammed with passengers as to completely vitiate the confined atmosphere. We have known instances where the gaseous emanations from the hold have been of such a character as to be especially offensive to the olfactory organ, and to blacken speedily any articles of silver that were exposed to its influence. The habits of the steerage passengers, moreover, are oftentimes so filthy as to render their part of the vessel little superior, in point of cleanliness, to a pigstie; and in some of the ships, where fever has recently prevailed, the boarding-officer at Grosse Island has actually had to lay down planks over the liquid filth and dirt which covered up the 'tween-decks to the depth of many inches, before he could force his way to the beds in which the unhappy passengers were dying. The food, also, has sometimes been so bad as to be productive of the worst effects: pork and beef in a state of high decomposition have been eaten, and these articles have become so offensive as to render it necessary to cast them into the sea. The captains of the vessels appear to have little concern for the welfare of those placed under their care so long as they have paid their fare, and they may wallow in filth or commit the most disgusting excesses without any exercise of authority on the part of the skipper. The Government, also, cannot be entirely freed from blame in permitting crazy vessels to be chartered, improper food to be shipped, and such multitudes of passengers to be taken on board, that necessary accommodation for them is out of the question. As a consequence, there is scarcely an emigrant vessel which crosses the Atlantic where fever does not break out either amongst the passengers or crew. The public are utterly ignorant of the sufferings which individuals in the steerage undergo, not only from improper accommodation, but from attacks of fever. Many die at sea the victims of typhus, and are speedily committed to the deep, without the real facts being brought to light, in order that when the ship gets into port the captain may exhibit a clean bill of health, and thus avoid detention under the quarantine regulations.

Another crying evil is, that many of their vessels either have no medical officers on board, or one without any legal qualification, or one who has engaged to exercise his vocation without any pay. We publish a letter in another part of our columns which will throw a little light upon this part of our subject. The fact is, that owners will engage any pretender to medical science to undertake the most responsible duties, without caring a rush whether he can diagnose a fever, or distinguish jaundice from scummo-y. Apprentices just out of their time, young men who have attended a few lectures, or druggists' assistants, are the class of persons who are too frequently chosen to watch over the lives and health of those who become passengers in emigrant ships, while the owners parade before the public view the important information that their vessel carries a surgeon on board. Never was there a deception more impudently practised, or more productive of evil consequences. Legitimate medical practitioners are thus prevented from obtaining a proper remuneration for their services, while the passengers are deprived of that

scientific superintendence which is necessary to preserve their health, or to restore it when their frames are invaded by disease. The consequence is that, when fever makes its appearance, it is almost sure to seize on numerous victims, and to advance unchecked to a fatal termination. We should like to be informed how many of those vessels which have recently conveyed to the American shores such multitudes of human beings afflicted with typhus carried properly qualified surgeons, and what medicines were at their command to combat the disease. The Government is bound to institute immediately a searching examination, and to take care for the future that mammon-loving merchants shall not increase their wealth by refusing to adequately remunerate a proper medical officer. No vessel should be allowed to put to sea without such a gentleman, who ought to be furnished with a chest well stored with surgical instruments and proper medicines.

No one can entertain a doubt that much suffering and many deaths might have been prevented if the Government agents at the different seaports had efficiently discharged their duties. The poor who emigrate are unable to protect themselves, and it is the duty of those who are in authority to undertake their defence. It is high time that filthy hulks should be prevented from being used as passenger-vessels, and that with improved shipping there should be better regulations to preserve, as far as possible, the health and comfort of the emigrants. The colonists, we hope, will, in self-defence, move in the matter, and we are sure that the members of the medical profession will use their talents and influence to urge persons in high official stations to institute such regulations as are best calculated to check those abuses which entail a vast amount of suffering upon helpless individuals.

MISFORTUNES IN A MADHOUSE.

ONLY a few months ago the Grove-house Asylum for Lunatics, at Bow, became renowned in consequence of the brutal conduct of two of the keepers towards an unfortunate maniac, who died from the injuries which they inflicted upon him. The principals of the establishment very properly courted a public investigation into the conduct of their inhuman servants, and the judge who presided at their trial severely animadverted upon their conduct, and sentenced them severally to three and six months' imprisonment. Scarcely has the excitement subsided, than the institution is again introduced to the notice of the public in consequence of the death of another insane patient in the asylum, from fracture of the ribs. On this occasion it appears that no one connected with the establishment is chargeable with having inflicted the injuries upon the sufferer which produced his death; but that he himself, in the silent hours of the night, became so obstreperous as to beat himself against the sides of the bedstead till he produced those fatal lesions which were subsequently discovered.

It is most unfortunate for this institution to have, within so short a space of time, two of its inmates die from violence, and it shows how careful the managers ought to be in selecting proper servants, and in giving proper attention to all the patients. In the case of violent maniacs, it is necessary that they should be placed under a degree of restraint which is compatible with their safety, and it is equally proper that there should be a careful superintendence of

them, that no serious mischief should result to themselves or others, when they become obstreperous. In the present case, the patient appears to have been left to himself during the night, none of the servants visiting him for many hours, when they find him bruised and mangled from his own violent efforts. Such a system of management cannot be too strongly condemned, and we trust that this event will be a warning for the future to all superintendents of lunatic asylums. The public have an opinion that in licensed private mad-houses many abuses still exist, and that the patients are even now doomed to occasional suffering either from improper treatment or culpable neglect. There is an impression, also, that keepers and nurses, not being allowed very high wages, seek every opportunity of using means to render their duties as light as possible. We do not pretend to say that this is the case in the asylum at Bow; but, however high the servants are remunerated there for their duties, they did not exercise that nocturnal vigilance which was necessary to prevent a patient from inflicting injuries upon himself which caused his death.

We would strongly advise the principal of Grove-house Asylum, Bow, that, as he on a former occasion very properly dismissed two savage keepers in his establishment, he will now discharge the sleepy ones, and that, to prevent any more manias from fracturing their ribs against the sides of the bedsteads, the wood or iron of which these articles are formed may be surrounded with a very soft padding of wool horsehair.

A VERY curious inquest was concluded this evening (Thursday) just as we were going to press, on the body of a poor man who died of alleged starvation, aided by pulmonary disease, in the union-house, Holborn. The peculiarity of the case consisted in these facts—1st. That twenty hours before his death he had applied at the Royal Free Hospital, and was denied admittance by Dr. Marsden, the founder of that institution. 2nd. That there were at the time, as is alleged, many unoccupied beds in that hospital. 3rd. That the inquest was held before Mr. T. Wakley, formerly the bitter opponent of that hospital, and since promoted to a seat on the committee, and the fatherhood of one of the surgeons.

We have a *verbatim* report of the proceedings, which we shall make matter of publication and notice in our next number.

LITERARY AND PARLIAMENTARY QUACKERY.

(LETTER FROM DR. EDYE AND SON.)
[To the Editor of the Medical Times]

SIR,—“Gracchos de seditione quærentes quis tulerit?” said the Romans. “Mr. Thomas Wakley indignant at quackery,” or, in other words, quarrelling with his own bread and butter, is a spectacle which the world, from habit, regards with more philosophy. We are an age tolerant of a well-sustained comicality.

We, Sir, are as much quacks as Mr. Wakley, ay, even to the second generation: we are avowed quacks too, proud of a *profession* so extensive; and, if our dander do rise at Wakley's verbal renegadism, it is because we can't afford to lose so distinguished an ornament as the coroner-journalist and surgical M.P. Till he gets us

our Charter we are not in a position to put up with his apostasy; and when the Charter does come, where—without Wakley—look for a president?

In retracing that worthy gentleman's career, I (Dr. E dye, senior) am lost in admiration at the wonderful point of development to which his daring genius has brought our art in England. See him addressing a Finsbury audience! How his *peculiar*, his *very peculiar* aims at party support, and profound schemes of parliamentary *business* are veiled in that face, those attitudes, and that voice, which recall so forcibly the heedless jackpudding of a Birtholomew fair! His head brooding over such other things, how complacently he fills open mouths with stale jokes! His bosom occupied by substantial matters so much nearer to it, how imitatively he M.P.-izes all characters—from Virtue's stern monitor up to Folly's glib buffoon! “Oh! the wonderful man!” I involuntarily exclaim, “would that my son would study, *nocte manequè*, that master of the science!”

And then turn to his coronership! Only remember how he managed that! How the *medici* were taught that it was to be all for their good! How *they* worked for it!—how *they* paid for it!—how *they* gave it him!—and then—(ah! ah! ah!)—and then—(ah! ah! ah!)—*how* he turned it “to their good”! *how* he “worked” it for them! *how* he made it “pay” them! how he gave it them! Ah! ah! ah! By Jove it was magnificent! Some of my Judaic brethren in Newman-street do a dashing thing now and then; but how their grandest *coup* fails in the comparison! The weak nerves of Lord Deaman were astounded at one of these clever moves! He gave judgment against the Coroner forsooth! How little he knew his man! Doctors “were injured,” said he, “law was twisted”, “evidence excluded.” But how else, or at what smaller price, could even Wakley have achieved so superb a stroke of judicial and political empiricism? Small matters, indeed, will be Hounslow inquests, like some of my own cases, if fellows like Wakley or myself must take our notions of legitimate practice from the simple-minded Chief Justice!

But if we would understand the full perfection of our chieftain's empiricism—an empiricism which the *sham* apostasy of his attacks on us only makes unique and more perfect—we must turn to his unrivalled and exquisite achievements in journalism.

Just as Messrs. MORISON and MOAT have their “Hygeist,” he has his *Lancet*, to cut up doctors as *they* doctrines, and circulate f—s as they pills. With what skill has he not managed his prices and cash accounts! Morison's popularity never got him raised prices for diminished wares! Thirteen-pence-halfpenny were to him high and low water-mark. But mark the worthy Chevalier of Argyle-street! While a shilling could be got for a small dose of journalism he took no less; when eightpence—he took that; when only sixpence—he meekly took that! But, did he stop there? Not he. When the small dose would not sell for a shilling, nor for eightpence, nor for sixpence, he unhesitatingly doubled the quantum! What ductile sagacity! How it reproduces us the barrister who, accused of taking pence on a brief, triumphantly replied:—“While my client had gold, I took that; when only silver, I took that; and when there were only coppers, I was too faithful to my cloth to disdain that!”

We advertise our highly-respectable firm: well, with all his popular disadvantages, Wakley will almost do as much! We, of course, have fifty cures for five patients; but what's that to Wakley's hundred copies for *one* reader? We publish laudations of our *skill*; but what are they to that magnificent hyperbole, when Wakley announced himself to Hudson—from that best of advertising vans—the House of Commons—as a man knowing *something* of surgery!

But the true test of a quack is, after all, his advertisements! They are the measure of his empirical greatness; and here how indisputably does our President in *posse* vindicate his pre-eminence! I declare that a few months' lease of his services in this line of business would make the fortune of Messrs. Mosses and Co., Professor Holloway, or myself. My difficulty has always been to get a man who, with the same fertile powers of imagination, can unite the same daring of assertion. Our “gentleman” would bluish himself into an apoplexy at the very idea of ushering into the world such *happy*—such heroic audacities as he perpetrates with the greatest ease and self-possession!

What a capital characteristic instance have we about “Lane's Lectures on Syphilis”! Just at a time (end of 1841) when your *Medical Times* was looking up, and his *Lancet* looking down, some striking *coup* was necessary, and out came the following telling, business-like advertisement:—

WAKLEY'S PERFORMANCE!!

Some four lectures were published, and in the ten subsequent volumes not another word (of *coups*) occurs about them!

WAKLEY'S PROMISES!!

“The first of a course of lectures on this subject”
“(syphilis) will be found in the present number of”
“our journal. Mr. Lane, the lecturer, has en-”
“joyed the most ample opportunities for making”
“himself thoroughly competent for the discussion”
“and treatment of this great branch of human”
“disease. Practitioners residing in the most”
“distant parts of the empire will now have the”
“opportunity of acquiring the best information”
“which the experience and practice of the London”
“institutions can afford the means of communi-”
“cating, regarding not only syphilis itself, but all”
“the complaints which simulate that direful,”
“odious, and destructive malady.”
“The demand for such a course of lectures has”
“been urgent and almost universal, many of our”
“professional readers having loudly complained”
“that the *Lancet* should have omitted nearly”
“twenty years without a series of discourses on”
“the subject appearing in our columns. If we”
“be not much deceived, we shall, in presenting”
“to them now the fruits of Mr. Lane's ample”
“experience and sagacious observation, remove”
“from their minds the accusation of a previous”
“neglect of duty.”
“We trust that one of the useful effects of”
“publishing this valuable course of lectures will”
“be the shutting out, now and for ever, of a dis-”
“gusting set of impostors from the wide field of”
“quackery. The number of victims which some”
“of these knaves have entrapped is enormous.”
“The folly of a moment, through a devilish”
“species of fraud and cunning, has been made, to”
“innumerable innocent sufferers, the medium”
“of gross extortion, and a source of most dis-”
“tressing mental suffering during a long period”
“of years. Instances of this description are,”
“in fact, almost numberless. Many of the”
“weak-minded victims of indiscretion and cre-”
“dulity will now, indeed, really discover that”
“knowledge is power.”—*Lancet*, Nov 13.

Now, is not this specimen capital? But no—you, Sir, are no authority. A man must know the arcana of a quack firm to comprehend all the cleverness of the *dashing coup*. The eminent

coroner, while writing it, knew, doubtless, that he should never be able to publish the 'course'; yet how confident the tone!—how big the hopes!—how large the promises! The younger *gobemouches* of the faculty must have almost wished to have had syphilis themselves, to study the wonderful series with more practical advantage. If, in their fervour, they ventured, *à la Ricord*, on the experiment, how were they "bold" when the subject-matter *did*—and the lectures did—*not* appear!

I pass by SCHÖNBEIN and his "magnificent" lectures; which, on the principle "omne ignotum pro magnifico," remain "ignota," and therefore, "magnificent" still!

I pass by, also, the "complete course" on Physiology, by Dr. Todd, whose "completeness" remains untouched by the publication of a fragment up to this day!

I likewise pass over "Liston, the first surgeon of Europe," whose writings were to be published in apt conjunction with Baillarger's "Grand Elucidations of Insanity." I pass by, too, Brodie, with some half-dozen other advertised and non-appearing "courses," though any one of the advertisements of the *paulo-post-futurum* series would have made the fortune of fifty George Robinses, and I turn with concentrated, breathless admiration to the ILLUSTRIOUS LIEBIG ABORTION. It was there that the quackery of medical advertising reached its *acme*! We shall never, never more see anything similar or even secondary to it!

WAKLEY'S PROMISE!!

"When we announce that amongst several"
"DISTINGUISHED AND NOVEL COURSES OF LECTURES"
"which we have secured for publication in"
"the enlarged and stamped numbers of the"
"Lancet, is one by the renowned PROFESSOR"
"LIEBIG, OF GIESSEN, ON CHEMISTRY as applied,
"in the great divisions of that science, to"
"MEDICINE, PHYSIOLOGY, AGRICULTURE, and"
"MANUFACTURES, it must be admitted that there"
"is no mode of conveyance which could be rationally"
"suggested that ought not to be employed for"
"transmitting a knowledge of a MORE IMPORTANT"
"AND VALUABLE COURSE OF LECTURES THAN"
"HAS EVER YET APPEARED IN PRINT, to the"
"remotest corners of the earth"!!!!!!

Can anything—could anything be finer? more catching? more dazzlingly deceptive? more "drawing," as we say? Yes! But (and mark the but) it is from the same pen! In the *Times* of June 22, 1844, Liebig is again advertised, and people are asked to buy the *Lancet* and see Liebig's "Discoveries which at the moment"
"of their development made the whole nervous"
"system of the discoverer thrill as if by an"
"electric shock, and the eyes of the observers"
"glisten with delight"!!! Conceive a better—finer—more glowing advertising climax! And then, to complete the perfection of the description, you have only to remember the subsequent *doing*—the sort of Liebigian "land of promise"—a fool's paradise indeed—into which the poor subscribers were led; viz.:—a few unfinished, trumped-up, commonplace lectures on commonplace, introductory, schoolboy chemistry—a miserable fragment of a more miserable series!—Ah! ah! ah! Such the affluence of his more than Wordsworthian poetry! As the *Times* says—"such the power of genius even in its most undisciplined moods!"

I am tempted to stop at this last achievement as a fit Waterloo for even this Wellington of quack advertisers; but no—better remains behind. Let me give you one of many inimitable ad-

vertisements on Müller—whose work was *not* given, *as usual*, in one-fifth part or less, simply because it was never given at all! Read, Sir—read—and I will give a thousand pounds if you can point out a man who could practise, with more coolness, a better hoax on a "discerning public"! It really is, what all the great advertised courses were to have been, "magnificent"!

"NATURAL PHILOSOPHY."

"will be continued weekly in that journal"
"without a single intermission until the Course"
"is completed."

"The value of this contribution to the sci-"
"entific records of this country may be duly"
"estimated by the fact, that the cost of the"
"original drawings and engravings alone has"
"exceeded the sum of Two Thousand Pounds."

But, if it was a dashing thing to announce, for weeks and months, a course with an unheard-of and impossible number of engravings—and costing thousands of guineas—and which, therefore, Wakley, from the beginning, (a) "wished they might get!"—what do you think of the way in which this more than Joseph Ady, of our business, managed when the awful day fixed for testing his promises came? The stratagem deserves immortality; and hence I historicize it with my own hand. First came a specious announcement of the receipt of an "immense amount of correspondence," deprecating the publication of the course! There were "hundreds" of people who objected to his spending so much money for them! They protested against receiving so many thousand "highly-finished engravings" gratis. The work was "something" too much to their advantage! The editor, sympathizing with his worthy correspondents, began, therefore, on the 27th of

(a) I see that actually *without making a promise or puff*, you have published these lectures in the *Pharmaceutical Times*, very gentlemanly, no doubt, but not the way to catch the public now-a-days.

March, to *doubt* what he should do. He would, however, so far oblige them as to pledge himself not to publish them for the present—he would, at all events, take time before forcing the "magnificent" work on his reluctant subscribers! The engravings were made of course—the work all ready for printing of course (for the day fixed for publishing them was but seven days off)—but still he really would deliberate! Another fortnight, and the discerning readers were told that the course, after all, was of a kind not to suit them! It, therefore, would really not be served up! The sciences of physics and meteorology, which originally were sciences "with which every medical man ought to be most intimately acquainted," and "which, therefore, we have secured for publication" were now found out to be "inapplicable to the readers of the *Lancet*!" Alas! for the "upwards of 1200 beautiful and highly-finished engravings"! Alas! for "the original cost of more than two thousand pounds"! Alas! also, for the thirteen hundred readers!!

And now, Sir, was there ever a better "sell"? Was it not magnificent? grand! gorgeous? unsurpassable? No—not quite that. As none but himself can be his parallel in this line of business—so none but he can surpass himself. In the *Lancet* of * * *

Your obedient servant,

JEROME EDEY AND SON.

[* * We must postpone to next week the conclusion of the letter of Doctors Edey and Son, to whom we must apologize for the long delay of their interesting communication.—ED.]

THE NATIONAL INSTITUTE.

The first annual general meeting of the members and Council of the National Institute of Medicine, Surgery, and Midwifery, was held, on Wednesday evening, at the Hanover-square Rooms. N. Clifton, Esq., was elected to the chair, and called on the secretary to read the report:—

At the termination of the first year since the establishment of the National Institute, the Council have much satisfaction in reporting the success which has hitherto attended their efforts to consolidate the organization of the general practitioners. Notwithstanding the indifference and torpor into which the profession had fallen in consequence of the withdrawal of the Government bills, when the enterprise of founding a permanent institution was first undertaken, and notwithstanding the variety of opinions which existed as to the most desirable policy for the General Practitioners to pursue, the principles adopted by the Council have received general support, and the National Institute is at this moment the most numerous and important, and, indeed, the only body representing the interests of this class in the profession.

The necessity of such a permanent association as the National Institute has been strikingly demonstrated by the recent proceedings in Parliament in reference to Medical Reform. The introduction of the Medical Registration Bill, and the appointment of a special committee of the House of Commons to inquire into its provisions, and to investigate the laws relating to the practice of medicine, required that there should be some efficient and authoritative Council ready to examine into the provisions of that measure, to watch the progress of affairs, and to represent and to impress upon the Minister the wishes and the objects of the general practitioners. Unless such an executive body, thoroughly familiar with this difficult question, be maintained in constant efficiency, it is manifest that a measure, no matter how detrimental it may be to the interests of the general practitioners, might be

adroitly and unexpectedly passed through the Legislature to the great dissatisfaction and injury of this body. The subject of medical reform has now arrived at such a critical juncture, and so imperatively demands an early settlement, that no lengthened period can possibly elapse before another medical bill will be presented to the Legislature, when the vigilance and deliberation of a duly-authorized body on the part of the general practitioners will be again required. Thus the experience of the past, and the imminent anticipations of the future, alike declare the necessity of maintaining, strengthening, and extending our present organization.

The most important subject that has engaged the attention of the Council during the past year has been the bill, already referred to, for the "*Registration of Qualified Medical Practitioners, and for amending the Laws relating to the Practice of Medicine in Great Britain and Ireland*," which the Council, after the most deliberate examination of its various provisions, and with a due reference to the fundamental principles which the Institute is established to carry out, thought it advisable to oppose. The Council have repeatedly stated by public advertisement their objections to this bill, so that the members have had ample opportunity to judge of their validity and importance; it may not, however, be unnecessary, on this occasion, to state one or two of the main arguments which influenced the Council in coming to their decision upon the measure. It may be said generally that the Registration Bill, whilst attempting to unsettle the existing relations of the profession, and to abrogate many useful laws, did not seek to establish any one of the more important principles for which the general practitioners have been so long contending, and which the formation of the National Institute was intended to realize.

The Committee of the National Association, and the Council of the National Institute, have alike asserted, from the very commencement of their labours, that the education and the examination of the general practitioners ought to be under the control of members of their own class, as the only certain means of securing that high standard of attainment which the importance and variety of their duties so unquestionably demand. The evidences of the truth of this position are too numerous to record, and some of the most remarkable must be so familiar to the minds of the members of the Institute that further reference to them is unnecessary. It is manifest that the general practitioners can exercise no efficient control over their own curriculum of study and standard of examination unless they are placed under a proper corporate organization, with a suitable code of laws, and an elective governing body. The National Institute seeks to obtain such an incorporation, and thus desires to give embodiment and permanency to the most essential principle relating to medical reform. The Registration Bill contained no provisions for such an incorporation; but, on the contrary, placed the control over the education of the general practitioners in the dictum of the Secretary of State.

The bill further expressly provided that, from the time of its becoming law, any young man *thenceforward* receiving his license and becoming a member should be entitled to practise all the branches of the profession upon a single qualification, so that it would be competent for a future members of the profession to practise either medicine, surgery, or midwifery, or to dispense medicines, without having been instructed in these branches, or having had their qualifications tested by any kind of examination; and thus, an anomaly that originated in the laxity and imperfection of medical discipline, whose existence at this time is the source of our dissensions, and of our weakness as a class, and which all enlightened men deeply deplore, would have been confirmed and perpetuated by legal enactment. The National Institute is founded upon the principle of admitting ALL qualified gentlemen now in actual practice as general practitioners to equal rights and privi-

leges; but the Council cannot too emphatically condemn a measure that would render education and examination in any one branch of the profession, more especially as respects the great body who must necessarily belong to the class of general practitioners, totally unnecessary to a title to practise, and that would thereby lower the attainments and destroy the status and respectability of the whole profession. In this respect the bill in question was far more objectionable than the measures brought forward by Sir James Graham; and the Council of the Institute were bound in duty to their constituents and in consistency with their principles to offer their distinct opposition to the scheme.

The twenty-eighth clause of the bill, which especially exempted chemists and druggists from the operation of the measure, appeared to the Council to be fraught with peril to the interests of the general practitioners, inasmuch as it provided that "all persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same, shall and may use, exercise, and carry on the same trade or business in such manner and as fully and amply, to all intents and purposes, as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this act."

The point upon which the decision of a judge in a new trial would turn, supposing even that their should be no defect in the wording and construction of the bill itself, would, of course, be the nature of the business of a chemist and druggist prior to the passing of this bill; and knowing, as we do, that the large majority of chemists and druggists, in pursuance of their business, actually practise as general practitioners, and knowing also how loosely medical and surgical practice is defined by the law, the Council feared that the druggists might be able, under an untried act, to establish their claims to practise medicine, and, consequently, that the protection the profession now enjoy would be seriously impaired and perhaps virtually destroyed. It was only after repeated trials that the Society of Apothecaries were enabled to obtain a judgment, under their act, to prohibit the chemists and druggists from practising as apothecaries, upon the ground that, before the year 1815, the business of the chemists and druggists did not embrace the practice of medicine; and the Council felt that an advantage that had been obtained with so much difficulty, and which, even now, can scarcely be said to be securely established, ought not be placed in jeopardy by a hasty and inconsiderate abolition of the act through which it was acquired.

There can be no doubt that new trials would take place under a new act, and the difficulty of obtaining a judgment in favour of the duly qualified medical practitioner would be much greater now than heretofore; inasmuch as the unqualified practice of chemists and druggists has become much more frequent and general, and the point to prove would be, not what was the business of a chemist and druggist before 1815, but what it was prior to the passing of this bill.

The provisions of the bill for the REGISTRATION of the profession, and the advantages which, in association with other clauses, they are assumed to confer, did not appear to the Council to be of sufficient weight to induce them to forego their acknowledged principles for the sake of assisting to carry into effect a partial and very questionable scheme, especially with the probability before them of the legal recognition of those principles. The Council are fully convinced of the expediency of registering the duly qualified practitioners of medicine, and also of admitting them to the enjoyment of equal rights and immunities; but they maintain now, as they have always maintained, that an equality of qualification should be the basis of an equality of privilege. Any bill that neglects to provide for an equality of qualification, or provides for it in the insufficient and objectionable manner proposed by this measure, and seeks nevertheless to establish an

equality of privilege for all future practitioners, will, most certainly, give great dissatisfaction, and would, if it should become law, be found injurious to the peace and welfare of the profession.

In the discussions that have taken place, particularly of late, on the subject of this Registration Bill, it seems to have been forgotten that it is the new members of the profession who would become obedient to the regulations of admission under a new system, and that both common sense and the general welfare require that a new system should be uniform, just, and comprehensive. The Apothecaries' Act was an act of indemnity for those in practice in the year 1815, when it became law; the terms of the charter, as agreed upon by Sir James Graham and the joint deputation representing the general practitioners, in the year 1845, provided for similar immunities: an indemnity of the same nature is also recognised as a principle upon which the National Institute is founded; but in neither instance has it ever been contemplated that the qualification for the future general practitioners should be diminished; on the contrary, it has always been desired and expected that a measure of medical reform should render the education required of every individual—to be licensed in future to practise generally in medicine, surgery, and midwifery—complete in all these branches; and that while the education was thus rendered complete, in reference to the nature and extent of the duties of the general practitioners, the standard of qualification should also be augmented, in reference to the advancement of medical and surgical knowledge.

The assumed advantages of registration under this bill, laying aside from immediate consideration the clauses restraining unqualified practice, are—the right of every practitioner, licensed under the act, to practise in every part of her Majesty's dominions, and to claim for advice, attendance, and medicines, in a court of law; together with the prohibition of any person giving medical evidence, or signing a medical certificate, unless he be duly registered. To the first subject of equality of rights, without equality of qualification, the Council have already objected, because they feel that whichever branch of the profession should conceive that its qualification was the most honourable or meritorious would entertain jealousy at the position occupied by the members of the other branches—a spirit that unhappily prevails too much at the present time, and which is now referred to with great regret, as being the cause of preventing a cordial and permanent co-operation for the general good; but which, under the circumstances proposed to be established by the bill, would be greatly and, perhaps, irremediably aggravated. The effect of the bill in this respect would also be to depress the standard of qualification to its lowest possible limit, so that there would soon be little difference between the general practitioners and the chemists and druggists, who are rapidly elevating their standard of scientific attainment. These two classes would be in a short time indiscriminately mingled, and a severe blow would thus be struck at the present high character and status of the general practitioners.

The eleventh clause, which provides that a licensed practitioner shall be allowed to charge for advice and medicines, is founded upon a just principle, but is not of sufficient practical utility to claim precedence over other essential measures which the bill fails to embrace. Not only has custom sanctioned the charging for visits and attendance by qualified medical men, but the courts of law have already decided in favour of such claims; as a matter of expediency, however, it may be safely stated that this particular clause would be very seldom acted upon, for medical men could never, under any circumstances, find it their interest to engage in frequent prosecutions; so that the bill in this respect would do little for the profession. The advantage comprised in the right to give medical evidence in a court of law is again merely affirmative of ex-

isting custom, and is of comparatively little practical importance, inasmuch as the evidence of an impostor could not now be received in a judicial court as the evidence of a medical man; and, on the other hand, every qualified man is at present admitted as a witness when medical testimony is required. The public would never permit any magistrate, judge, or coroner, to suppress or to refuse to receive valuable medical evidence.

In reference to those clauses of the bill protecting the exclusive right to practise of the regularly licensed practitioner, and rendering it penal under a summary process for any individual (chemists and druggists acting as medical practitioners excepted) to practise without a license, the Council entertained great doubts whether such clauses could pass the Legislature in their prescribed form, and at the late period of the session when the bill was introduced; and they believed also that those provisions might be so altered in committee as to be far less stringent and useful than the existing Apothecaries' Act. The Council, indeed, had no confidence that these clauses would pass through the committee of the House, and they were unwilling to relinquish the Apothecaries' Act, which, by the new construction put upon its provisions, has now become of increased value, in order to obtain a measure which would not, in all probability, realize even the advantages it seemed to promise. All that is valuable in the proposed Registration Bill might have been obtained without the abrogation of the penal clauses of the Apothecaries' Act; and the interpretation put upon those clauses, making illegal practice a misdemeanour punishable by a summary process, is so recent, that it is more politic to wait until the new interpretation be fully established in the courts of law before we give our consent to any measure that shall supersede this act. The Registration Bill, therefore, was brought forward at a very inopportune period. The two cases that have been tried have confirmed the new interpretation, and the Council trust, now that the Registration Bill is withdrawn, that the Apothecaries' Society will see the necessity of protecting the interests of their licentiates. For these various considerations the Council did not feel themselves justified in lending their support to the bill; and from the situation in which they were placed in reference to it, and also from the limited time that was allowed for its progress through the House, they saw no chance of having a fair opportunity of remedying its numerous defects, and of making it conformable to what they believe to be the views and interests of the general practitioners.

The Council have published in their last number of "Transactions" a report of their interview with the Right Hon. Sir George Grey in relation to this bill, and the general question of medical reform, and they beg to refer the members to those "Transactions" for a detailed account of their proceedings. They have much pleasure, however, in repeating that Sir George Grey promised that no measure of medical reform should be undertaken to which they were not admitted concurrent parties; so that it may be hoped that the claims of the general practitioners will be fully heard and respected. The special committee appointed by the House of Commons to inquire into the subject of medical reform have not yet completed their labours, and the dissolution of Parliament prevented their making a report or publishing the evidence. The representatives of the Colleges of Physicians and Surgeons were alone examined, but the Council of the Institute took the necessary measures to express their views before the special committee when their turn for examination should arrive. Should the committee be renewed at the next session of Parliament, an opportunity will be afforded for the Council fully to state their views.

With the view of promoting professional concord, and of uniting in a common interest the provincial and metropolitan practitioners, the Council advert with pleasure to the conversations,

held on the 13th of April last, at which a considerable number of the provincial members attended, and expressed the highest satisfaction at the proceedings of the evening, and of the opportunity for social intercourse which the meeting afforded. The Council hope to be able to repeat such reunions, for which the central situation of the metropolis, and the various professional and social connections which most of the provincial members have necessarily formed in it, render it peculiarly advantageous.

The Council, after careful deliberation, have framed a code of by-laws for the government of the Institute, which have been circulated among the members, and will be submitted this evening for adoption. In consideration of the various opinions and different modes of practice among the members of the Institute, the Council have prepared such rules as they think will be most acceptable to the large majority of the members, and most conducive to the honour and stability of the Institute; and they beg to observe, that in a work so complicated and difficult, the most careful deliberation was required to include the wishes and views of all classes of members without introducing conflicting regulations. They have been desirous that the by-laws should be considered a prototype for the government of a corporation which they are, and have been, endeavouring to obtain with anxious solicitude; and that they should be also in consonance with the terms of the charter agreed upon by the Right Hon. Sir J. Graham and the joint deputation. These laws have already been published, and it has afforded satisfaction to find that the objections offered have been few; and that, in several instances, the Council have been enabled to adopt the alterations that have been suggested.

The donations to the library of the Institute, from the members during the year, amount to upwards of 300 volumes, many of them very valuable works. The Council trust that the members will continue to take an especial interest in this department of the Institute, and exert themselves to promote its success, particularly as the facilities for circulation are so rapidly increasing all over the country, as to make it an object of the most extensive utility not only to the metropolitan but also to the provincial members.

In determining the vacancies in the Council for the present year, and the mode of nominating and electing new members, the Council have acted upon the rules relating to those duties set forth in the proposed by-laws; they have not thus anticipated the by-laws by acting upon them before they were adopted, because they cannot be considered laws until they have been confirmed by the members; but it being necessary to declare vacancies, and to elect new members, the Council have adopted in the first instance that mode which they believe to be the best, and which they are about to propose for adoption by the members, to regulate the business of future elections.

The following vacancies will take place in the Council this year:—

METROPOLITAN.—Mr. Pennington, elected president; Mr. Clifton and Mr. Fuller, vice-presidents; Mr. Clayton, Mr. Nussey, and Mr. J. Sim Smith, trustees; Mr. Dodd and Mr. Tegar, treasurers; Mr. Davis, Mr. Lavies, and Mr. Moore.

PROVINCIAL.—Mr. Martin, vice-president; Mr. Isaac Hunt, Bedford; Mr. Allison, East Retford; Mr. Bryan, Northampton; Mr. Coward, South Shields; Mr. Dickinson, Ulverston; Mr. Hughes, Stafford; Mr. Hunt, Manchester; Mr. Lowe, Bristol; Mr. Sleight, Hull; Mr. Thompson, Nottingham; Mr. Rogerson, Liverpool; and Mr. Morley, Midhurst.

THE TREASURERS' REPORT.

In presenting the Treasurers' report, the Council beg to state that when the members of the National Association were first canvassed, 1300 gentlemen declared their willingness to join the National Institute, and were accordingly enrolled as members; of this number (including

also other gentlemen who have since joined) 900 have paid their subscriptions for the past year. It is hoped that those members whose subscriptions are yet due will take an early opportunity of forwarding them to the treasurers, as otherwise it is proposed by the new by-laws to deprive those gentlemen of the exercise of the rights and privileges of a member of the Institute.

The Treasurers' Report of Expenditure from April, 1846, to the 31st of July, 1847 (sixteen months).

The Chairman observed, that a great part of the report had been occupied with a review of the proceedings in reference to the late proposed bill; and he would on that occasion merely observe that, whatever dissatisfaction had been in some quarters expressed at the conduct of the Council, in that respect he felt confident that the members would find that they had acted throughout strictly in accordance with the principles of the Institute, and for the welfare of the profession. He was sure that neither could be satisfied until a far more comprehensive measure should be placed before the Legislature than that of Mr. Wakley.

It was moved by J. Bowling, Esq., and seconded by G. I. Squibb, Esq., that the report now read be received, adopted, and entered on the minutes.

The Chairman said that the next business was to fill up the vacancies in the Council, as eleven of the metropolitan members go out, and thirteen of the members in the country. According to the regulations in the proposed by-laws, which had been circulated among the members, many members had nominated gentlemen as candidates for a seat in the Council; the list, however, was not sufficiently comprehensive, and it would be necessary to add to their number. Any gentleman would be at liberty to name another, whose name would, with the rest, be placed before the whole body for election. In case sufficient gentlemen were not named, a list had been prepared for the convenience of the meeting, which it would be in the discretion of the meeting to adopt or reject. Those names were not dictated to the meeting, they were suggested to expedite business, in supplying the deficiency of the nomination by the members.

A Gentleman suggested that the by-laws should first be passed.

The Chairman observed that in that case the elections would be brought under their operation; and thus the nomination of members for the Council could not be then proceeded with, and the list would be incomplete (chap. 2, clause 4). If the meeting were agreeable, they would proceed as at the first general meeting for the formation of the Institute.

The names of gentlemen proposed were then read.

Several gentlemen complained that lists of the members of the Institute had not reached them, and that thus they had not had an opportunity of choosing the most suitable council for the next year.

It was explained by the Chairman that the list had been published, and had been advertised as to be had on application. The printing and transmission of the list to so numerous a body as the members of the Institute would have been a formidable difficulty, if it had been attempted to send to each member a copy.

Mr. Charles Clarke would wish, at this stage of the proceedings, to make a few observations. It struck him that he was one of a large class

who had joined the National Institute at its formation, and who had been proud of the principles which were then announced; but he was sorry to say that those principles, in his opinion, had not been carried out as they ought to have been. The National Institute, instead of having been the vanguard of the medical profession, had been rather the instrument of the Apothecaries' Company, to whose principles and interests it had succumbed. He had no interest in making these derogatory remarks, nor had he any personal feeling in the matter—personally, he knew very few of the Council: he believed them to be honourable men, but he thought they had not remained true to the principle of the Institute in the matter of medical reform. Until the opposition to the recent Registration Bill, he had supported the Council, but so satisfied had he been that in opposing it they were placing the members in a false position, that he had strenuously set his face against them. He would frankly acknowledge himself the author of a letter which had appeared in the *Lancet*, signed "A Member of the Institute," in which he called the Council "the Judas Council of the Institute." He was anxious that the Institute should flourish, and that the general practitioners should have a head and home, as it had been expressed. As for the College of Surgeons, it could not, and never ought to, become their head. Let those who might wish to be *pure* surgeons or *pure* physicians go to the two colleges respectively: for his part, he was anxious to see the general practitioners have one of their own. Had the bill passed, it would at least have set the corporations at loggerheads, and out of that good might have been derived by this body. The resolution that he would propose, with the best wishes for the Institute, was to the effect that no person connected directly or indirectly with the management of the Apothecaries' Society should be eligible for election to a seat in the Council of the Institute. He would wish to see the Institute quite clear of all corporate bodies at present in existence; he would wish to see the battle of the general practitioners fought by the Institute singly and alone; he felt confident that the work would then be done better, for the meeting might depend upon it that the corporate bodies would seek their own interests, and not those of the body.

Mr. G. Bird would second the motion with great pleasure.

Mr. Ansell said it afforded to him and to every one who, like him, had from the first taken a lively interest and an active part in the affairs of the Institute, pleasure to hear the comments of a meeting like that upon those subjects which had occupied the minds of the executive body. So far from looking at it as a matter of congratulation, that Mr. Clarke had not extended his remarks further, he wished that he had done so; he wished that those numerous calumnious statements which had gone forth could only be brought out at such a meeting as that, where they might be met and answered satisfactorily, as he was sure those advanced by Mr. Clarke might be now. He appealed to those who had watched the conduct of the Institute, whether or not in every step the Council had not most scrupulously determined carefully to observe a strict distinction between their own body and the Apothecaries' Society, or any other body? Whether from the commencement of their labours they had not taken every precaution to avoid mixing themselves up with the Apothecaries' Society? It was true that at times they had found it expedient, and he believed the judgment of that meeting would justify their opinion, to have the co-operation of the Apothecaries' Society, without whose assistance they must have come to a standstill. It was well known that in 1844, when Sir James Graham's bill was under consideration, the Apothecaries' Company had published a document, and had obtained a large amount of support from the general practitioners throughout the country. That document proved to the minds of the profession throughout the country that the Society had been acting on

the broadest possible basis for the public good. They said they were prepared to give up their power to another body so soon as it should be shown that the general practitioners should not be the sufferers by such a step. After such conduct, he thought the Council would have been wrong if they had thrown any obstacle in the way of the support of the Apothecaries' Society. The Council had had to appear before the Government of the country, and what had the Government said? "We cannot get rid of charters; you are dissatisfied with the Apothecaries' Society; we will supersede that body with their own consent, but we cannot do it without." As one of the members of that deputation, he would say that, throughout the whole of the proceedings, the Apothecaries' Society had acted in good faith. The moment a measure could be proposed to the Minister, to put the general practitioners in a better position, they were ready to execute a deed to get rid of all the powers they possessed. They had, therefore, acted with good faith, and doubtless they would continue to do the same. He was one who thought the Apothecaries' Society behind the spirit of the age: it was not the society for the present day; he would not then enter into the considerations which had more and more fastened the conviction of this truth upon their minds, but the belief had grown upon them. Under these circumstances, the Apothecaries' Company could and were willing to do much to assist them in bringing their position and views before the Minister of the day; it ought not, therefore, to be said, that the Institute had been subservient to the Apothecaries' Company.

He would say one word with respect to the Medical Registration Bill. Mr. Clarke, in his remarks, seemed to infer that if, by any means, the profession had been plunged in chaos and confusion, the general practitioners would have been the better. Now, he thought that in such a chaos the Minister of the day would be left to the advice of the corporations, he could not see that such a chaotic confusion could be of service to the body; but he apprehended that very grave evils would be likely to spring out of it. The Apothecaries' Bill had served the purpose of the profession up to a certain point, and the privileges enjoyed under it should not be lightly given up until something were propounded more positively beneficial. The resolution of Mr. Clarke appeared to him to tend to exclude, by its operation, a gentleman who was a general practitioner, practising on the principle that medicine and surgery are one science—such a man, for instance, as Mr. Bacot. With respect to their worthy president, he could state that the Council of the College of Surgeons had elected him the Senior Fellow of the College—an honour which might be expected to operate as an inducement to lead him to desert the Institute, should such men be refused. He thought that to do so would be to act most unwisely. He would not further detain the meeting.

Mr. G. Bird said he was very glad that he had seconded Mr. Clarke's resolution, as it had drawn from Mr. Ansell what to him appeared to be a most complete exculpation, and had relieved his mind of the undue influence which he had no doubt had been felt by many others, of the considerations to which Mr. Ansell had alluded. With the permission of the meeting he would retire from his position as the seconder of the resolution.

Mr. James Bird wished every one to understand that from the first it had been stated in the most unequivocal terms, that no new Apothecaries' Society should be formed with the concurrence of that Institution. He knew very well that every possible means had been made use of to delude and mislead the profession into a belief that this was nothing more than an apothecaries' movement. It was no such thing. He was sorry that with many these attempts had been successful, and that in listening to the delusion they had been led into error and misconception. It had been stated that it was not as apothecaries, not as surgeons, but as general practitioners

they wished to organize the body, otherwise they would not have sought a new incorporation. The Apothecaries' Society distinctly stated, that to another Society of Apothecaries they would not surrender their privileges. This had been their language to a deputation from Manchester, that unless a charter were granted to examine not only in medicine, midwifery, and pharmacy, but in surgery also, they would not surrender their powers. That was, he thought, an answer to the insinuation that this was an apothecaries' movement. He would assert that it was for the examination in surgical as well as medical knowledge, making together the qualification of the general practitioner, that they had formed the National Institute.

Mr. Clarke had paid attention to Mr. Ansell's speech, and was of opinion that he had thought more of the Apothecaries' Society than of this. He considered that it would look better in the public eye if the two bodies acted separately.

Mr. Ansell said, that the temporary junction was dictated by expediency; the joint deputation was at an end: they had no present connection with the society.

The resolution of Mr. Clarke, not being seconded, fell to the ground.

The Chairman would be happy to receive from the meeting the names of any gentlemen as candidates for seats in the Council.

It was then moved by H. P. Fuller, Esq., seconded by J. Colthurst, Esq., of Clifton, and carried, that John Nussey, Esq., J. Sim Smith, Esq., Isaac Hurst, Esq. (of Bedford), and James Clayton, Esq., be elected trustees of the Institute.

It was also moved by J. Nicolson, Esq., seconded by J. Probert, Esq., and carried, that John Dodd, Esq., and Edward Tegar, Esq., be appointed treasurers.

It was resolved, on the motion of F. D. Bennett, Esq., seconded by L. E. Davis, Esq., that Silas Stedman, F. D. Bennett, and F. A. B. Bonney, Esqrs., be auditors.

It was moved by R. Tanner, Esq., seconded by R. Wallace, Esq., and carried, that W. Mayor and N. Grant, Esqrs., be appointed scrutineers.

The Chairman then said, they had come now to the most important business of the evening—the by-laws. The secretary would first read them over, and afterwards the chapters would be put, one after another, from the chair.

On putting the fifth clause of the second chapter—

"No member interested in the sale of any nostrum or specific remedy, or keeping a shop for the retail of drugs, shall be eligible as a member of the Council"—

Mr. Southey, of Cambridge, begged to offer an objection to the clause, as it divided the members of the Institute into two bodies. He should have thought that the experience of what the College of Surgeons had done, in making some of the members eligible to seats in the Council and others not, would have deterred the Council, on the present occasion, from putting forth such a proposition. In his opinion, that conduct had been the proximate cause of the formation of this Institute, and he thought it savoured very much of vanity in the Council to propose this measure. Why should they be exempt from sitting in company with gentlemen who kept shops? He strongly objected to anything that would tend to lead the Council to look down upon any portion of the Institute. He moved that the clause be expunged.

Mr. Clarke said, if no one else would second the proposition of Mr. Southey, he would, but only to keep it before the meeting. He must condemn any opposition to the clause: for although he had before freely condemned the Council, while he thought they were wrong, he must, in this matter, give them great credit for having made this clause a part of the by-laws. As he kept an open surgery himself, it might be thought that he would oppose the insertion of the clause; but he thought that if he, for his own interest or convenience, thought proper to do so, he ought not to wish to sit in the Council.

His remark had reference to the latter part, for as to any member of the Institute selling empirical nostrums, he hoped no one would think of such a thing.

Mr. Bowling, of Hammersmith, said he thought that the members of the Institute ought to set an example to the chemists and druggists, and show them that they would not tread in their shoes, by meddling with matters that did not belong to them. He had a strong feeling upon the subject, and would be sorry to see the clause expunged.

Mr. Southee would agree to the clause, if it were extended so as to apply to a membership of the Institute as well as of the Council; but if it stood in its present shape, two classes would be made, and many would secede. If it were proposed to declare that, from the granting of the charter, every member of this Institute keeping an open shop should give it up, he would support such a proposition. Let not the Council make two classes in the Institute; he would rather exclude the keepers of open surgeries altogether.

The Chairman: That is impossible.

Mr. Fuller, of Piccadilly, said, this Institution was formed on the principle of admitting all who had the legal qualification and were in general practice, nothing was said about shops; and they could not, therefore, turn round upon those who kept such, and say, "You shall not be members." But the by-laws are now to be formed, and the important question now came—What shall be the nature and composition of the Council? They were hoping that, by-and-by, things would get into that state when it would not be necessary for men of liberal education to sell drugs like chemists and druggists; but, unless something could be done to prevent those tradesmen acting as general practitioners, it would be almost impracticable, in many places, for the young man to establish himself unless he kept what was recognised by poor people as a *doctor's shop*. He thought that many of them must have known instances of gentlemen beginning their career by shutting up their house, who, after spending all their capital, were obliged to open a shop. They could, therefore, do nothing directly to promote the extinction of this practice without an act of Parliament, and their efforts must, at present, be directed to those measures which would elevate their class of the profession. The clause proposed in the by-laws was an indication of what it was wished the Institute should become. Practically it would work itself out, for such persons would be little known—"No, no"—they would be principally the young members, and would not be balloted in.

The Chairman said it was very important that the members should be of one mind on the subject of the by-laws, as such agreement might bear very materially on their future operation, and he thought it would not much matter if this clause were left out altogether. The members of the Council would always be chosen or rejected by the body of the Institute, and there would be, he thought, no substantial reason for restricting their choice.

Mr. James Bird said he knew that a feeling was rife amongst many that no person should be eligible for membership of the Institute who kept an open shop, and from the minute subdivision of the profession in many rural districts he could well understand it. He hoped it would be borne in mind that these by-laws were the type of what the Institute was wished to become under a future charter; they had endeavoured to draw up such a code as should require very little alteration for the government of the body when incorporated, and, as had been necessary in 1815, the existing body must first be provided for, and then regard must be had to the future. They could not shut out any who had a legal title to practise, whether they kept a shop or not; but the Council had thought it desirable, as far as it was possible to indicate in some manner the judgment of the Institute upon the practice, and in order to show their ultimate intention, to disconnect themselves from anything that would tend to

identify them with a spirit of trade; they thought it was a proper course to mark that distinction by rendering them ineligible for a seat in the Council. It was for the meeting, and not for the Council, to say whether the course should be adopted or not.

Mr. Southee did not think either of the gentlemen who had spoken had shown any reason why the clause should pass; it was not a *post facto* law, and none would suffer if it were rejected. If it were necessary to make the distinction spoken of, then let it apply to future admissions to the Institute; but, at least, let those who now formed the body be allowed to judge who out of their own number were fit to sit in the Council, otherwise a feeling of degradation would be inevitable.

Mr. Burnett, of Alton, considered that the main reason why the Institute had been so much opposed by the Colleges of Physicians and of Surgeons was, that the members of those bodies had no cause of fear in those who kept open shops. When the Pharmaceutical Society were trying to obtain their charter, no serious opposition was raised, and it was granted at once. He thought that, if it were understood that the general practitioners were to keep open shops, they had little hope of being able to raise the standing of their profession in the eyes of the public or of the profession, and the colleges would be glad to find that they had so acted. If the younger members of the profession in London felt the necessity of keeping open shop, what must be said of those in the country? Yet he, for nineteen years, had practised in the provinces, and had never yielded to such supposed necessity. He determined from the first to assert his position as a gentleman, and the son of a gentleman; and, treating it as a question of principle, he resolved to do nothing not reconcilable with his standing. He thought that, if it was desirable to raise the position of the profession, it was necessary to enforce some such law as the present, in the framing of which he thought the Council had fairly exercised their judgment.

The clause was then put to the meeting and maintained, four hands only being held up against it.

On clause 5, chap. 3, being put—"No proprietor nor vender of any empirical nostrum can be admitted as a member of the Institute"—

Mr. Southee proposed to add, "nor any one keeping an open shop for the sale of drugs."

The Chairman stated, that such a question was already settled in the constitution of the Institute.

Mr. Southee contended that such a change might most properly be made to apply to all future admissions.

Mr. Clapham strongly opposed the proposition. The amendment, not being seconded, fell to the ground.

On chap. 4 being submitted,

Mr. G. Bird moved to insert a clause, "That in the event of any medical bill being brought before Parliament, or in the event of any negotiation between the Council and the Government, a general meeting should be called to ascertain the opinion of the members thereupon." He wished he could believe what had been asserted in an earlier part of the meeting, that the conduct of the Council had given great satisfaction; for his own part, he feared that anything but satisfaction was the feeling of the body of the Institute at their conduct in respect to the Registration Bill. Whether that feeling was well or ill grounded was no part of the question then; but he could not help saying, in reference to that bill, and he said it without offence, that the conduct of the Council had been characterized more by ingenuity and antagonism than by fair dealing; and he thought that evidence of such dissatisfaction would be given when the time came round for paying the subscriptions; he thought that the protest already received was but the first of other indications of that dissatisfaction. He would not press the resolution, but would ask the Council to speak one word that might give the members the assurance that, when such times as he had spoken of might come

round, they would be called together to be enlightened and consulted. All he wanted was some guarantee that no important steps should be taken by the Council on behalf of the Institute with the Government without a public meeting.

The Chairman reminded the speaker of the eighth clause, viz.—"A special general meeting shall be convened on a written requisition to the Council, signed by twenty-one members, specifying the business to be brought forward. Such meeting shall take place within one month from the delivery of such requisition."

Mr. Bird was aware of that clause, but he would have the evil specifically provided for; he thought that, if the Council had acted in the spirit of the motion at first, great dissatisfaction would have been avoided.

The Chairman said, they were now engaged in making by-laws which he hoped would conduce to the welfare of the members of the Institute, long after such matters as Mr. Bird had mentioned were forgotten; and although he wished every gentleman to have the fullest opportunity of expressing his opinion, and providing for its adoption by the meeting, he thought that no expedient, however important, for supplying a temporary want should have place among the permanent laws of the body. If any gentleman would propose any special instruction to the Council, they would be happy to receive it. He thought that every person must see that, by the publicity of a public meeting, many negotiations with the Government would be rendered abortive. The Council had not shrunk, nor did they shrink, from deliberation, but they had been most anxious to avoid anything that might damnify the cause that all had at heart. Their course had been most difficult, because, in addition to the ordinary obstacles in their path, they had been assailed by the most violent and gross calumnies. The character of the source from whence those calumnies came had led the Institute to take no notice of them, although some of the members might have been deluded. He thought that when the members saw the difficulties which the Council had had to encounter, and remembering that they had not all the elements of a correct judgment before them, they would feel it only just to pause before passing judgment on the Council.

Mr. Ancell said it had been from the first distinctly stated that, from whatever quarter a good bill might come, it should be entertained; but he thought that the gentleman who had wished the Council to give a pledge to take no step without a public meeting was not aware that the Government had summoned the Council at a notice of only two days. Up to that time the Council had no reason but to be proud of the conduct of the profession towards them; but, if confidence was to be voted in the Council one day to be withdrawn the next, what could be done? He only asked them to continue that confidence in the Council which they had already honoured it with, and he firmly believed that before many months their charter would be obtained. He only asked them to abstain from a hasty judgement, and to wait for the time when all the circumstances which had guided their conduct might be exposed without risk to those high interests which all had at heart. As to the assertion, that they had acted in a spirit of antagonism, so far from that, the most gross abuse that had been showered upon them had not drawn from them anything to justify the expression. He hoped the Council would continue to act as they had done, and he was sure every general practitioner would have cause to be thankful. He would add, that when Sir James Graham brought in his last bill, the Government told the representatives of the general practitioners that, if they came before it as surgeons, the Government could only recognise the College of Surgeons; but now that they were united as practising medicine, surgery, and midwifery, the Government gave them access, and promised that no step should be taken in which they were not concurrent parties.

Mr. G. Bird stated that he had no idea, in

making his motion, of impugning the motives of the Council: quite the reverse; he had only introduced it in order to assure the members that they would be consulted.

Mr. Bird's resolution was then submitted, when two hands were held up for it, and the rest against: thus it was lost.

The remaining by-laws were then passed without opposition. In chap. 10, clause 10, the time for keeping a set of books was extended from seven to fourteen days, and the time allowed to provincial members (clause 8) was extended to twenty-eight days.

The Chairman then stated that the business of the meeting had been transacted, and congratulated the meeting on the little diversity of opinion which had occurred.

A vote of thanks to the Chairman concluded the proceedings.

NOTE FROM MR. HEALEY.

[To the Editor of the Medical Times.]

SIR,—I have been honoured by a very formal attack in one of your contemporaries, in relation to my electoral contest at Stoke-upon-Trent. My only object in noticing the writer is to apprise you that to a person who habitually substitutes fiction for fact, and the language of St. Giles's for gentlemanly comment, there can be no becoming response but silence, and the quality such circumstances naturally connect with it.

I have the honour to be, Sir,

Your obedient servant,

T. PIERCE HEALEY.

Connaught-square, Aug. 19, 1847.

THE LATE DR. J. R. LYNCH.

[To the Editor of the Medical Times.]

SIR,—I have this morning received a circular requesting me to attend a public meeting to-morrow, to take into consideration the destitute condition to which the widow and orphans of the late Dr. J. R. Lynch are reduced by his premature death. This meeting I am, from age and its corresponding infirmities, unable to attend; but the letter that I have received may be turned to some useful account if you think the following observations are to the purpose, and will give them insertion in your hebdomadal.

In the year 1788 a society was set on foot for the especial purpose of affording relief to the widows and orphans of medical men in London and its vicinity, who, from the various accidents and contingencies to which the medical profession is liable, are left in poverty or destitution.

The subscription to this society is only £1. 1s. half-yearly, and this for a limited time only.

Had Dr. Lynch been three or four years ago, a member of this society, his widow would at once receive £30 a year for herself, and £12 a year for each of her three helpless children, making together £66 a year; and, as a committee is appointed to take into consideration the safety and propriety of increasing the amount of each grant, there is a strong probability that next year the amount will be greater.

More than £36,000 has been distributed among persons eligible to receive assistance; and at present thirty-three widows and seventeen orphans are receiving grants half-yearly.

The circular which I have received contains the names of ten or more members of the medical profession, strongly advocating the claims of this unfortunate lady and her children, and among them are many of well-known philanthropy and liberality; and without liberal assistance the Widows and Orphans Society could not support itself; but only one of these is a member of the Society for the Relief of Widows and Orphans! When it is considered that to those medical men whose circumstances are unpromising, two guineas a year will secure to their widows and orphans from three to five guineas or more every month, it seems wonderful that they should not avail themselves of this advan-

tage; and it is equally wonderful that those to whom two guineas a year is of comparatively trifling value should not contribute that sum annually for the widows and orphans of their more afflicted brethren.

The funded property of the society amounts to £47,000. The Princess Sophia and the Duchess of Gloucester have been for many years annual benefactors, and a few of the nobility and gentry have shown their good feeling to the medical profession by giving contributions; but generally the widows and orphans of medical men are cared for only by their brethren of the profession.

I remain, Sir, yours,

AN ANCIENT MEMBER.

MIDLAND CIRCUIT.—WARWICK, Aug. 6.

MOUSLEY v. KIRBY.

(Before Lord Denman and a Special Jury.)

This was an action upon the case for libel.

Mr. Whitehurst, Q.C., Mr. Humfrey, Q.C., and Mr. Mellor, were for the plaintiff; Mr. Waddington, Mr. Heyes, and Mr. Macauley, appeared for the defendant.

The litigant parties are both medical men, residing in Atherstone, the former being the surgeon for the Atherstone district of the Atherstone Union. On the 19th of last December a poor woman, of the name of Williams, was run over, and sustained a very bad fracture of one of her legs. Mr. Mousley and his partner, Mr. Hardford, attended the poor woman, as it was admitted, with skill and humanity; their object was to prevent amputation if possible, and after some time the patient seemed to be recovering and going on well; but owing, as was supposed, to a too premature use of the injured limb, she went back, and the defendant was called in, who though fit to represent the case to the board of guardians as one in which proper medical skill had not been displayed. The board of guardians immediately put the matter in train for inquiry, and the result was a unanimous vote in favour of the treatment Mr. Mousley had adopted in the case in question. We may mention, the patient subsequently died. The present action was brought against Dr. Kirby for the words he had uttered when complaining to the board of guardians. The object Mr. Mousley had in view was stated to be merely to have a public retraction, and not to put damages, or even costs, into his pocket.

Mr. Waddington stated that, if such was the plaintiff's only object, he had no objection on the part of Dr. Kirby to state that the plaintiff's humanity had never been called in question, and he now had no hesitation in admitting his skill; but, at the time the complaint was made, he (Dr. Kirby) was not aware of the nature of the accident.

Lord Denman said, as a general rule, it would be as well for medical men not to call in question the skill of their brethren unless they had informed themselves of all the circumstances necessary to their forming a proper and correct estimate.

A verdict was then taken by consent for the plaintiff. Damages 40s.

GOSSIP OF THE WEEK.

WAR-OFFICE, Aug. 13.—88th Foot: Assistant-Surg. John Shaw Willes, M.D., from 17th Foot, to be Assist.-Surg., vice Dods, promoted in 3rd West India Regiment.—3rd West India Regiment: Assist.-Surg. George Douglas Dods, M.D., from 88th Foot, to be Surg., vice Thomas Rhys.

NAVAL APPOINTMENTS.—Acting Deputy Medical Inspector A. Allen, to Plymouth Hospital.—Surgeons: J. Moody, to the Cambrian; E. H. Cree, to the Fury; W. R. Dalton, J. G. Risk, and A. Brown, to the Crocodile; J. Andrews (a), to the Marion convict ship.—Assistant-Surgeons: W. G. McClure and J. Fayer, to the Victory; C. G. Campbell, to the Avenger; C. S. Hugo,

to the Trincomalee; H. C. S. Wilson, to the Fury; J. L. Johnston, to the Cambrian.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having previously undergone the necessary examinations for the "Fellowship," before the Court of Examiners, were admitted by the Council "Fellows" of the college, in pursuance of the charter recently granted to that institution, viz.:—Messrs. Robert Woollaston, Conduit-street West, Hyde-park; William Henry Smith, Fonthill-place, Clapham-road; James Williams, Dalston-terrace, Dalston; Bernard Wight Holt, Abingdon-terrace, Westminster, assistant-surgeon to Westminster Hospital; Alfred Poland, Cloak-lane, City; William Fisher, Kendal; and Athol Archibald Wood Johnson, Suffolk-place, Pall-mall East. On the 13th inst., viz.:—A. Godfray, J. Rose, E. Muriel, G. T. Yelloly, and A. Williams.

APOTHECARIES' HALL.—Gentlemen admitted members August 12: Benj. Fielding Mathew, Joseph Meldoun Dempsey, and Thomas Green.

UNIVERSITY OF EDINBURGH.—The annual graduation of Doctors in Medicine took place on Monday, in the graduation-hall of the college, when fifty-eight gentlemen had the honour of receiving that degree.

MUNIFICENT LEGACY.—The funds of King's College Hospital have just received an addition of £1000, by a legacy under the will of the late Miss Colyer, of Farningham, Kent. Such bequests are of infinite importance to an institution which, like this hospital, has not as yet acquired any permanent sources of income not liable to fluctuation from year to year.

FEVER AT MARLBOROUGH-STREET POLICE COURT.—On Mr. Bingham taking his seat on Friday morning he was surprised at being informed that a malignant fever was raging in the court, and that the messenger and his family, consisting of six persons, who live on the premises, were lying dangerously ill of fever of a most infectious nature. The infection is supposed to have originated in consequence of the immense number of poor Irish who have latterly been brought to this court, some of them in a very unhealthy state. Mr. Bingham has ordered the necessary precautions to be taken to prevent the further spread of the fever.

HEALTH OF LIVERPOOL.—The *Liverpool Albion* appends to the quarterly return of mortality with regard to Liverpool, issued by the Registrar-General, the following gratifying statement:—"Since the above return was made there has been a very considerable alteration in the aspect of affairs in this town, and we are happy to state that the change is for the better. The evils above enumerated have considerably or altogether abated. There is no longer an excessive influx of Irish paupers; the parochial authorities can accommodate the few sick who remain on our hands with ease; and but few cases of fever are reported in the several districts of the town. The committees of the vestry are no longer beset with difficulties, but find themselves in a condition to give up some of their temporary hospitals, and to return the Government their hulk, the Lancaster, which was sent to the Mersey as an hospital ship. The nuisance arising from the privies still continues. Thousands of cesspools send up their pestiferous exhalations into the atmosphere; and it is not too much to say, that, till these contaminating nuisances with which the town is dotted in all directions are done away with, Liverpool will never be either healthy or sweet. At present, Edinburgh itself is not so celebrated for fetid odours."

Houses of refuge, similar to those in London and Paris, are about to be established at Constantinople and on the Bosphorus. It is very urgently proposed to have establishments in the principal provinces of the empire for regular gratuitous advice and distribution of medicine, upon the same plan as the one at Galata-Sérail, where more than 20,000 invalids secure relief annually.

DEATH IN A LUNATIC ASYLUM.—Yesterday an adjourned inquest was held before Mr. Baker and a jury, at the Five Bells, Bow, on the body

(Continued from page 504.)

LECTURE VII.

My second order of medicinal substances belonging to the organic kingdom is composed of "drugs the active properties of which depend chiefly upon a neutral bitter principle." The drugs of which I have hitherto treated owed their activity to alkaloids possessing marked chemical properties, capable of distinct separation, and employed either in their pure form or in that of salts artificially prepared. They claimed our attention from their importance, and, as it were, their superior composition. The drugs which we have now to consider deserve the next place, from their general utility and their numbers. There is another reason, besides, why I am anxious to enter at once upon this class, namely, the difficulty which I have experienced in arranging it. All the others were comparatively easy; but this, from various causes, was perplexing. The imperfection of analysis, the question as to which of several principles was the efficient one, the doubt as to the nature of the bitter principle itself, were all points for reflection, and called for thought and method. It will be remembered that the alkaloids possess the property of bitterness, and that to the most intense degree. We may consider it in them as subsidiary, possibly as a safeguard against incautious administration. We are now, however, to consider the bitter principle itself. This is neutral, chemically speaking; contains oxygen, hydrogen, and carbon; appears sometimes in the crystalline and at others in the amorphous form, and has that peculiarity of taste which has become proverbial from the natural repugnance which almost every one experiences with regard to it. Still, medically speaking, bitters are an important class of medicaments. Cullen, indeed, tells us that they only are real tonics; but, without admitting the truth of this assertion in its fullest extent, we shall not hesitate to allow great efficiency to numerous remedies possessed of this property. Nay, we see vomiting readily produced, and narcotic effects occasioned, by bitters given in considerable doses to man; and all are aware of their poisonous effects upon the lower tribes of animal beings. That bitters should be looked upon as medicinal, and that they should be resorted to as remedies, we might think likely, by reasoning *a priori*, when we recollect that certain secretions essential to digestion are copiously poured out, possessing this characteristic in a marked

degree. Regarding bitterness, then, as an index of injurious qualities, or of such substances as it was intended should be avoided in health, yet, as a principle, essential, as indispensable to our systems, and requiring to be appropriately supplied in certain states of health, I proceed to enumerate their chief effects upon the frame. Bitters give tone to the stomach, increase the appetite, and promote digestion; they are, besides, essentially anthelmintic, many having long enjoyed a reputation as specifics; and, in truth, in the class we have now to enter upon we shall find some of the most useful expedients for the expulsion when generated, and the prevention afterwards, of the internal parasitical worms. Most of the bitters have been used as remedies in intermittent fevers, and, doubtless, in many instances with good effect. They have been supposed to be emmenagogue also, though they are so probably only secondarily, from the general improvement which they are qualified to effect in the whole state of health.

The arrangement which appears to me to be the best of this class will be that founded on the appearance of the principle when pure, viz., crystalline, amorphous, or in the form of extract:—

I. Bitter Principle—Crystalline.

17. Quassine, obtained from *picramnia excelsa* si-
maruba amara.
18. Gentianine " *gentiana lutea*.
19. Calumbine " *coccylus palmatus*.
20. Cusparine " *galipea cusparia*.
21. Salseparine " *smilax officinalis*.
22. Elaterine " *momordica elate-*
rium.
23. Rhein? " *rheum palmatum*,
compactum, emodi.
24. Scillitine " *squilla maritima*.

II. Bitter Principle—Amorphous.

25. Absinthine, obtained from *artemisia absin-*
thium.
26. Cetrarine " *cetraria islandica*.
27. Lupuline " *humulus lupulus*.
28. Lactucine " *lactuca sativa*.
29. Pareirine " *pareira brava*.
30. Cantharine " *cassia lanceolata*,
obovata, elongata.

III. Bitter Principle—In the Form of Extract.

31. Aloesin, obtained from *aloes socotrina*, bar-
badensis, hepatica.
32. Colocynthine " *cucumis colocyn-*
this.

33. Rhamnine " *rhemnus catharti-*
cus.
34. Taraxacine " *leontodon taraxa-*
cum.
35. Diosmine " *diosma crenata*.
36. Ergotine " *secale cornutum*.
37. Scipentarine " *anistolochia serpen-*
taria.
28. Cascavilline " *croton eleutheria*.

17. Quassine, the active principle of the quassia and simaruba, was discovered by Wiggers; is described as freely soluble in alcohol, less so in ether, soluble in 200 parts of water, and as appearing in the form of small white prisms. Its formula is $C_{10}H_{16}O_5$.

Quassia yields a pure bitter, being neither astringent nor aromatic. Its effects are tonic and anthelmintic; for ascarides it may be employed as an enema. It is a good vehicle for chalybeates. The only official preparation is the infusion.

18. Gentianine is neutral, intensely bitter, appearing in yellow crystals, slightly soluble in water, freely so in alcohol and ether; but it is a question whether or no this be a pure substance, or a compound of an acid with the bitter principle.

Gentian is tonic and anthelmintic. It is useful in dyspepsia, especially of the atonic form. Its preparations are the compound infusion, the compound tincture, the extract, and the compound mixture.

19. Calumbine, the undoubted active principle of the calumba, is intensely bitter, insoluble in water, soluble in alcohol, ether, and in diluted acids. It crystallizes in the form of rhombic prisms.

Calumba is a pure bitter, being perfectly free from astringency. It is a very valuable tonic, imparting tone and allaying irritability; thus it is often of service in the sickness during pregnancy, in the debility after parturition, and in the chronic form of dysentery and diarrhoea.

Calumbine, the citric principle of calumba, is spoken of as a decided narcotic.

The preparations of calumba are the infusion and the tincture.

20. Cusparine, the bitter and the supposed most important principle of the cusparia or Angustura bark, exists in it in the proportion of one and a half per cent., is crystalline, somewhat acrid, is moderately soluble in water, freely so in alcohol.

Cusparia is a valuable tonic, and is one of

those of great use in the advanced periods of such fevers as implicate the mucous membranes, in dysentery, and chronic diarrhoea, such as we see in this as well as in warmer climates.

The only official preparation is the infusion.

21. I have placed salseparina in this order and division on the authority of M. Thubœuf. He describes this as the active principle of sarsaparilla; when pure, white, crystalline, radiated, little soluble in cold, but perfectly so in boiling water; and he maintains that this is identical with the sulfacine of M. Folchi, and the parigine of M. Palotta.

M. Cullerier states that he has found decided antiphlogistic properties in this principle, salseparina. Palotta says it produces nausea, vomiting, sweating, depression of the pulse; and Dr. Hancock claims for sarsaparilla, when good and properly prepared, similar properties. I entertain no doubt of the utility of sarsaparilla in cases of shattered health, especially when occasioned by the injurious effects of mineral or animal poisons upon the system. The improvement in the appearance of flabby ulcers, and in the aspect of patients when thus treated, cannot be mistaken, though a doubt may fairly be raised whether such amendment be due to any one isolated principle.

The most esteemed variety is the red Jamaica, and its preparations are a simple and compound decoction, a syrup, and an extract.

22. Elaterine.—There can be no question of elaterium possessing active properties, nor that those properties are due to a distinct principle. This is colourless, appearing in the form of satiny prisms with a rhombic base; without odour, but of an intensely bitter and somewhat acrid taste.

Elaterium, in the form of extract prepared as directed by the Pharmacopœia, is, through the means of its active principle, a powerful irritant, producing violent effects both as a cathartic and an emetic. The evacuations which result are watery; hence this proves a valuable remedy when judiciously ordered and appropriately given in certain forms of dropsy. It will act as a purgative when administered either in the form of an enema or as a suppository.

23. Rhein:—Great doubts are entertained respecting the active principle of rhubarb. By Brandes it is referred to an acid, which he terms rhabarberin. By Hornemann it is thought to be a substance altogether different, and which he calls rheumine. Peretti maintains that the active principle is a resin, which purges strongly in doses of ten or twelve grains without griping. Again, the rhabarberin of Nani, of Caventou, of Pfaff, and of Brandes, appear all to differ from each other. For the present, then, we must consider the point as undecided, and simply regard the obvious qualities of this substance as a bitter and stomachic, an aperient, and an astringent—a combination of qualities implying, as is the case, an assemblage of antagonistic principles. Rhubarb is tonic, stomachic, and, exhibited in small doses, in combination with a mild mercurial, an excellent alterative in cases of dyspepsia. It is an admirable medicine in disturbed states of digestion, when the tongue continues furred after the exhibition of active remedies.

It is aperient, and is thought especially to excite the action of the liver, and to stimulate the small intestines. To keep up its purgative effect, however, the combination of aloes is usually necessary, when it forms a very serviceable corrective of habitual constipation. The combination of astringency with aperient qualities would point out the use of rhubarb in cases where mild action upon the bowels was desirable in the first place, and a sedative afterwards. This is so generally known that this constitutes a popular remedy for sudden attacks in the bowels, which in very many cases it effectually cures.

The preparations of rhubarb are the powder, the infusion, the extract, and the compound tincture.

24. Scillitine is a crystalline, bitter substance, found in the squill by Landerer, and considered by him to be its chief component. Squill is

highly irritant when externally applied, or taken internally. In small doses, (two or three grains), it will produce an incessantly vomiting, and purging, and in larger doses diuresis and increased secretion from the mucous membrane of the lungs.

It is a valuable remedy when the bronchial tubes are loaded, and it is one of the best of diuretics in dropsy; and of the best in bronchitis. It is rarely used as a means of evacuating fluids, when effused into internal cavities; yet, after active means have been employed, it is often valuable, and especially so when, in children, it is probable water has been secreted into the ventricles of the brain.

The preparations of squill are the dried root, the acetate, the oxymel, and the tincture.

The amorphous bitter principles will next engage our attention.

A COURSE

OF

LECTURES ON SURGERY,

BY

SAMUEL COOPER, Esq., F.R.S.,

Professor of Surgery to University College, London;
Consulting Surgeon to London University Hospital, &c.

LECTURE XIV.

GENTLEMEN,—I was treating, at the close of my last lecture, of hospital gangrene, which is sometimes called phagedæna, or hospital sore: one of the worst forms of mortification, and one which is perhaps the most formidable and fatal. It is chiefly met with in army hospitals, though sometimes it occurs in civil hospitals, particularly where the wards are very much crowded with wounded patients, or patients having ulcers. In the Hôtel Dieu at Paris there has been often very great mortality from this cause. There is a dark crimson line along the integuments while it is spreading; deep purple redness is visible. I stated that it spares no textures, not even the bones; it attacks the cellular tissue, and leaves the blood-vessels exposed. If a ligature be put on these vessels to prevent hemorrhage, it cuts through; and if a tourniquet be applied, it may stop the hemorrhage, but it will increase the gangrene. We now come to speak of the causes of hospital gangrene. It is peculiar, I have observed to you, in being contagious, but you cannot explain its cause always on the principle of infection; there must be some other cause for the beginning of the complaint; and you now look for this in the state of the atmosphere and constitution. Where wounded persons are crowded very much together, and many under the same roof are affected with ulcers, it generally originates. I told you the question is rife, whether the phagedænic ulceration may not be the same disease as hospital gangrene; it is believed that there is a poisonous principle generated in the atmosphere which produces hospital gangrene, leading the wounds or ulcers to take this form of gangrene; therefore, we can explain the rapid extension of the disease in some hospitals, without supposing that the infection has been conveyed from one patient to another by using the same sponges or dressings: it is from the noxious character of the atmosphere in which the patients lie. Before I speak of the manner of treating this disorder, I must say that the constitutional symptoms are not always so severe as you might be led to expect. There is in some cases a white tongue, rapid pulse, and some other febrile symptoms; and in some there is a great deal of vomiting, and a typhoid state comes on early. When there is much constitutional disturbance there is very slight chance of recovery. With respect to the prognosis of this disease, we must recollect that its treatment is better understood now than it was formerly. In many diseases greater benefit arises from internal treatment than from external, as in the case of persons who lie much in bed,

and especially in bad compound fractures, lacerations of the veins, and so forth. In these cases, indeed, treatment is more successful than external treatment is hospital gangrene it is quite the reverse. You will make use chiefly of external applications. But I am bound to be totally opposite to the use of emetics; emetics have been tried, but the reports that have been made of their effects have been very ambiguous. Purgatives in the early stages of disease are more useful—mild purgatives—citric acid, when the bowels are able to bear it, is also very useful. Opium, too, must not be forgotten, as from the swelling there is often a great deal of pain. Venesection, also, has been tried, and various opinions are entertained of the good effects, as, from the malignity of this disease, gangrene will often attack the puncture itself. In the treatment of hospital gangrene, you must, whenever it is possible, remove the exciting cause; sometimes this is most likely to be accomplished by removing the patient into another ward. It has been observed that hospital gangrene is most likely to occur in crowded buildings, and in those buildings which stand on a low marshy soil, especially in hot weather. This should not be forgotten in the treatment you employ, as from the want of attention in these matters the best medicinal treatment may be rendered unavailing. Then, the external treatment, which I said was most efficacious, consists in the employment of strong escharotics. The French surgeons formerly applied the actual cautery, but have since tried a solution of chloride of lime, and speak very highly of it—more so than English surgeons think it deserves. Lister thought that by the use of this remedy the complaint might be considered as conquered. "Now," said he, "hospital gangrene will be a mere trifle, now we have it in our power." The same success, however, has not attended its use in our country, and hospital gangrene is still a formidable disease. We find, however, that very strong escharotics do tend very much to stop the progress of this mortification. The liquor arsenicalis, diluted with an equal quantity of water, is a very valuable remedy. Blackader tried it, and with considerable success. He used to wash the parts with a solution of carbonate of potash, and, after removing as much of the pulpy substance as he could, he dipped lint in the solution and put it on the part, changing the lint every half-hour. You might, perhaps, suppose that by applying arsenic to the wound there would be a danger of poisoning the part, but it is found that gangrene produces in the flesh an insusceptibility of injury from poison applied in this manner. An application which is now preferred universally, is that of strong nitric acid. If the sloughs are thick they must be incised before the acid is used: here we see a deviation from the general rule, of leaving sloughs to the operation of nature; but the surgeon is obliged to divide the slough, as the nitric acid would not act from the surface. When the sloughs are removed the skin must be covered with a thick coating of some substance to prevent injury from contact with the nitric acid, which is then applied till the slough becomes of an ash colour, dry, and insensible. At this time opium must be administered, as the patient will often suffer much pain. After the sloughs are removed, granulation begins over the part, which is sometimes attacked again, when you must repeat the treatment with nitric acid. Under the frequent return of these attacks patients will, however, often sink.

We have also mortifications arising from deleterious substances introduced into the system, as by bad food. This kind of the disorder is endemic, occurring chiefly in certain parts of the Continent where rye is an article of general consumption. It is a very remarkable form of gangrene, but, as it is very rarely met with, I shall have very little to say concerning it. It begins with no previous inflammation; the patient suffers a great deal from drowsiness and numbness; there is much febrile disturbance; the limbs swell (it usually attacks the lower extremities); but no other remarkable symptoms occur. Often

the part attacked passes into a cold, stony, and cold. We find that the disease sometimes begins in the centre of the limb, and it may commonly happen that after it has passed to the knee the leg will drop, and the mortification.

In another variety of this disease, the patient, when about to be attacked, becomes ill, and passes into the typhoid state. The treatment is obvious: the originating cause must be removed; where it arises from bad food, the food must be improved and generous diet added—wine, ammonia, &c.

I make these remarks rather as matters of curiosity than for practical use, as the disease seldom occurs in this country, although I remember about three years ago meeting with a case in one of the medical journals of the day of this disease attacking a child.

I must now direct your attention to some points to be observed in mortification. With respect, first, to amputation, all practical men agree that, in cases of bad mechanical injuries, this is best done early, before mortification begins, or even inflammation comes on. The usefulness of this practice must be obvious: for, if you defer amputation till mortification comes on, you take the patient just when his system is least able to bear the operation; whereas, by prompt action you may anticipate these effects, and give the patient the best chance of recovery.

Another rule is to attend to the line of demarcation. Where mortification arises from internal causes, you would never be justified in amputating until this line is clearly marked, because by the absence of this line the system is shown to be still in that unfavourable state which induced disease in the limb, and, should you operate under these circumstances, you would have the stump attacked; it is therefore a rule in surgery, that where mortification arises from internal causes, you must never amputate till this line is formed. When the line exists you can see that the parts are dead on one side, and that the other exhibits a bright red colour, as if from the presence of arterial blood. You will then endeavour to strengthen the patient with nutritious diet; he will go through the operation better, and the results will be more likely to be favourable. At the same time you should distinctly understand that this rule of incising for the appearance of the line of demarcation is intended to apply only to mortification from internal causes; if we were to act on it in cases of mortification from external injuries, as gunshot wounds, for instance, the patient would either die before mortification had ceased, or sink into a low state, in which amputation would not be practicable—a state which very rapidly follows these injuries. Now and then the gangrene will go down to the bone, and no operation will be required at all. I remember a case under Mr. Liston: an old woman was brought in, with what was thought to be gangrenæ senilis; the arm was attacked up to the shoulder, and nothing but the saw was used; the stump healed readily, and she went out very soon. As a general rule, it is better that the reparation of the slough should be the work of nature; but, like all other general rules, this is not without exceptions; they may be summed up under two heads: the first, when one part of the slough is perfectly loose, and the other is attached, in which case the cutting away of the loose portion will diminish the effluvia and hasten the healing process; the second, when the whole portion of a limb is mortified; although in this last, as in the case above related, nature would have in time accomplished the work. Much judgment is required in determining upon the course to be pursued with respect to some cases, and promptness is often the means of saving life.

This form of mortification will often bring on coma and delirium; the intellectual functions are more readily disturbed; and this is again an exception to the rule of waiting for the line of demarcation.

In cases where the constitution is bad, slight

excitations of the hand will be very likely to be followed by mortification of the fingers. It has been said that you are not to break through the rule, even when you have a bad constitution to deal with; but, whatever course you may take, the chances are very bad, and, if you leave the patient to the chances of the mortification, you leave him in a very hopeless condition. Of course an operation would not go down well in health, but you must take that point which, at the time seems best; the same may be said of mortification from injury of the internal organs, or where it follows popliteal aneurism, or from pressure of the bandage.

These are some of the leading rules of amputation in gangrene.

We next come to consider some other kinds of inflammation, which may be considered as specific or peculiar; and, first, of boils. The chief difficulty of boils arises from their always containing a quantity of dead cellular tissue called the core, and situated in the centre of the inflamed part. It is a prominent, hard, very red, and painful circumscribed swelling of various dimensions, though, perhaps, never exceeding a pigeon's egg in size; it projects above the surrounding skin, which it raises, and below it there is dead cellular tissue, which is accompanied by an ichorous matter which is often tinged with blood; it is a very painful kind of inflammation, though not extensive; and, when you remember that it projects above the skin, you cannot be surprised at the patient's complaints of the sore. Its figure is that of a cone, having its base considerably below the surface. If it is left to nature it will turn white in the centre, and about the sixth day will burst, and, if the core is extruded, will heal; but if it is retained recovery will be impeded. One particular in which it differs from carbuncle is, that very often there are two or three, or perhaps more, existing simultaneously on the body. We meet with it very much in drunkards, and in persons whose stomachs are very much abused; also after acute fevers, after scarlet fevers, and severe attacks of erysipelas. The treatment of boils is various: a few believe that they are best dispersed—some blacken them—some apply tepid water. A surer plan is to poultice the part, and make an early opening, so that the cellular tissue may have an opportunity to escape; the part will then generally granulate, and heal without much trouble. In some cases they occur for a very long time, and in these we find that the stomach is in a very bad condition. I attended a young lady, about eighteen years of age, who had four or five of these boils in different parts of the body, which were of long continuance, and gave her great uneasiness.

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART XIII.

NERVOUS FORCE.

The animal organism is provided with a set of organs through which the animal receives impressions from without, and is enabled to direct the motions of the voluntary muscles. These organs constitute the cerebro-spinal nervous system, which is composed principally of an infinite number of ramifications disseminated through the whole body of the animal, and, finally, united in a central mass, constituted by the brain and spinal marrow. If one of these ramifications be cut or tied in the living animal, and the portion remaining in connection with the cerebro-spinal mass be then touched with a red-hot iron, or with a piece of caustic potash, or wounded with a needle, or pulled with pincers, the animal will give evident signs of pain; upon irritating the portion below the section or ligation in the same manner, no signs of pain will be manifested, but the muscles in which the excited nerve spreads its ramifications will be observed to

contract. If these excitations be practised upon the intact nerve, the contractions and signs of pain will be exhibited simultaneously. Finally, if the nerve be tied at two points at some distance from one another, and the portion intervening between the two ligatures be then excited, neither contractions nor signs of pain will be elicited. The nerves belonging to the cerebro-spinal system have accordingly no other office than to transmit or propagate the action of the stimuli applied to them. This action is twofold, viz., transmission of a sensation to the brain, and excitation of contractions in the muscles.

Bell, Magendie, Müller, Panizza, and other physiologists have discovered that there are in the organism certain nerves which, when excited, induce solely muscular contractions, and others which, submitted to the same irritation, induce solely pain. This is the case with the anterior and posterior roots of the spinal nerves, and with some other nervous branches. Flourens, Longet, and other physiologists have distinguished in the nervous centres likewise portions presiding solely over the sensations, and others presiding solely over the muscular movements.

A bundle of nerves consists of a great number of filaments, every one of which possesses, individually and separately, the faculty to transmit the dictates of the will, or the excitation of any stimulus, independent of the other filaments.

Besides the cerebro spinal system, there exists another system of nerves in the organism, viz., the ganglionic system. This latter is composed of ramifications distributed principally to the apparatus to which the organic vital functions are intrusted; these ramifications run gradually, intermix with each other, and present in their interstices a globular substance, which seems likewise to exist in the central masses. The ganglionic system, although having numerous connections with the cerebro-spinal system, induces neither movements nor sensations when excited. The excitation of nerves belonging to this system is propagated slowly, and persists some time after the withdrawal of the stimulus. A muscle, severed for a certain time from its communication with the centres (ganglia) of this system, loses the faculty of contracting under the influence of the excitation of its cerebro-spinal nerves.

These few general remarks on the nervous system will suffice to show the importance of the results arrived at in our investigations of the physiological action of the electric current (*vide* Part XII.).

The following are the principal differences discovered to exist between the effects of electric irritation upon the nerves, and those produced upon these organs by other exciting agents, such as heat, mechanical and chemical action, &c.:

1. Electricity is the only stimulus capable to excite at one time sensation, at another contraction, according to the different direction in which it passes through the nerve.

2. The electric current, when sent transversely into a nerve, fails to produce any of the phenomena usually resulting from excitation of the latter.

3. After protracted action upon a nerve, the electric current ceases to produce any effect upon the latter.

4. The electric current alone possesses the faculty to modify the excitability of a nerve, even to the point of speedily annihilating it when circulating in a certain direction, and of preventing or augmenting it, on the contrary, when circulating in the reverse direction.

5. Finally, the electric current alone has the power to revive the excitability of a nerve when this excitability is extinct, or nearly so, with respect to all other stimulating agents.

The nature of the action of the electric current upon the nerves leads us to infer that there exists a certain analogy between this current and the nervous force. But are we to conclude from this that the nervous force and the electric current are identical? Certainly not; and yet we find this identity between the two forces but too often

admitted as one of the most clearly demonstrated experimental truths.

Let us ask, in the first place, "Do we discover, with our present means of experimentation, the existence of the electric current in the nerves of a living animal? Can this current exist in these organs?—and, this existence proved or admitted, is it placed in conditions adapted to invest it with the characteristics of the nervous force?"

The muscular electric current, of which we have treated in a preceding part, owes its origin to certain chemical actions occurring in the muscles. We saw that the nerves have no direct influence upon the production of this current; and we found, in our experiments upon this subject, that their office seems limited to that of a body of low conducting power, communicating with certain parts of the muscles.

It would occupy too much time to report the numerous experiments that have been made with a view to establish or to disprove the existence of the electric current in the nerves. May it suffice to state, that the most conscientious and best established conclusion seems to be this:—*In the actual state of science, and with the means of experimentation at present at our command, we are unable to discover the slightest sign or trace of the existence of an electric current in the nerves of living animals.*

It has been asserted that, when steel needles are implanted in the muscles of a living animal, perpendicularly to the direction of the muscular fibrils, the needles become magnetic, more particularly at the moment that the muscles contract. This has led some physiologists to the conclusion that there actually exists an electric current in the nerves, and that the circle is established as in an electro-dynamic spiral or cylinder. The author has repeated the experiments, upon the supposed results of which this conclusion is based: he introduced steel or iron needles into the muscles of living animals, perpendicularly to the direction of the muscular fibrils, and in every other possible direction; he used for these experiments needles of a highly perfect astatic system, and even those of Lebaillif's sideroscope. The results proved invariably negative—no magnetization of the needles was observed.

The author placed the thigh and leg of a recently prepared frog into the axis of a spiral, made of varnished copper wire; the extremities of the spiral were in communication with those of another, smaller spiral, which had a soft iron wire placed in its axis. The author excited the nerve of the frog to see whether a current of induction would pass through the spiral and magnetize the iron wire: the results proved invariably negative. A great many other experiments, made by the author and also by Louget, gave the same results. These physiologists did not in one single instance obtain evident and constant signs of an electric current circulating in the nerves.

Besides, if we consult our present knowledge of the properties of electricity and of the laws of its propagation, we find it altogether impossible to conceive the existence of an electric current circulating in the nerves. To enable us to conceive the passage of an electric current from one extremity of the nervous system to the other, the nerve should admit of comparison to a metallic wire covered with varnish, or some other insulating substance; which is by no means the case. A current starting from the brain under the influence of the will, and passing through the nerves to arrive finally at the muscles, could not be interrupted by the ligature of the nerve; but the propagation of the nervous force is interrupted by this means. The circulation of the electric current in the nerves would require, moreover, that the nervous system should form a closed circle; and the labours of the anatomists have not yet by any means demonstrated the existence of a similar disposition of the nerves, more particularly in their last ramifications in the muscular masses, where this disposition would be more especially necessary.

The author has frequently attempted an ex-

periment which, had it given a positive result, would have proved indirectly that the nervous system forms a complete chain for the electric current. He laid bare one of the nerves of a living animal in two points at a distance from its passage—in the upper part of the thigh, and lower extremity of the leg. He introduced the leg into the axis of a spiral, made of varnished copper wire, and communicating by its extremities with another, smaller spiral, with a soft iron wire placed in its axis. He then discharged an electric current across the nerve so prepared; but he never observed constant signs of a current of induction in the spiral, as would certainly have been the case if the current had circulated in the species of spiral supposed to be formed by the nervous ramifications distributed in the muscles.

We are accordingly led to the conclusion that the electric current does not naturally exist in the nerves of a living animal. The laws of its propagation require certain conditions, for which we look in vain in the nervous system; the propagation of the nervous force is interrupted by causes which fail to produce the same effect upon the electric current.

The identity of the nervous force with the force of electricity being thus disproved, we are led to inquire: what is the relation existing between the nervous force and electricity or the electric current?

There exists between electricity and the nervous force an analogy which, though less evident, is yet of the same kind with that existing between the former and light and heat. In the course of our observations on the phenomena presented by electric fishes, we saw that the electric faculty possessed by these animals is subject to the nervous system.

A crystal of tourmalin evolves electricity when heated: this fact leads us to assume the existence of a more or less intimate relation between electricity and heat. The phenomena observed in electric fishes prove the existence of a similar relation between electricity and the nervous force. In the case of the tourmalin, electricity is derived from caloric, in consequence of the form of the constituent molecules of the tourmalin. In the electric fishes, the nervous force is transformed into electricity under the influence of the particular structure of the organs of these animals. Let us now examine how electricity can excite nervous phenomena. We know that heat and chemical or mechanical actions possess the same faculty to excite the nerves, and to induce sensation and muscular motions, as electricity. Are we to conclude from this that mechanical, chemical, and caloric actions are transformed into electric currents? We know of no fact or circumstance tending to support a similar hypothesis; if, however, we were, notwithstanding this, to suppose a transformation of the kind to take place, this might be done with some appearance of probability with respect to the chemical actions, but surely not with respect to mechanical actions and to the actions of heat. The mere section of a body never produces an electric current; and it is impossible to establish any comparison between a muscle and a body capable of thermo-electricity. Mechanic and caloric actions can only be looked upon as divers causes of a molecular movement.

It may, however, be asked, does the cause of the nervous phenomena reside in these molecular movements of the substance of the nerves, or is it attributable to a disturbance in the equilibrium of the ether diffused through the nerves? And is this disturbance the consequence of a particular movement of the ether supposed to constitute what we call the *nervous fluid*?

We can give no satisfactory reply to these important questions: the facts requisite to solve them are, as yet, wanting.

The author thinks, however, that it is impossible to explain and interpret the nervous phenomena by the sole movement of the ponderable molecules of the nerves.

We will now proceed to the examination of a phenomenon, discovered some years ago by the

author, and to which the English philosophers have given the name *contraction by induction*.

If the nerve of a galvanoscopic frog be placed upon one or both thighs of a frog disposed in the ordinary way, and the poles of a pile be then applied upon the lumbar plexus of the latter, the contractions of the thigh muscles of the frog will be attended with simultaneous contractions of the muscles of the galvanoscopic leg. The author observed the same phenomenon in another experiment, where he had placed the nerve of the galvanoscopic frog upon the thigh muscle of a rabbit, which he caused to contract by subjecting the nerve spreading its ramifications in that muscle to the action of an electric current. He observed the same phenomenon when substituting for the electric current any other stimulus applied to the spinal marrow or lumbar plexus. He repeated the same experiments, but with this difference, that he placed very fine layers of various substances between the nerve of the galvanoscopic frog and the muscular surface where the induced contraction is developed; the interposition of a gold leaf or of a very thin layer of mica or of glazed paper prevents the manifestation of the phenomenon; but the interposition of a sheet of fine paper imbibed with water does not interfere with the induced contractions of the galvanoscopic leg.

From these facts we may draw the following conclusions:—

1. The induced contractions of the galvanoscopic frog are not attributable to the electric current.

2. We are led to assume, on the contrary, that an electric discharge occurs during the contraction of a muscle; in other words, that the contraction of a muscle is attended with development of electricity.

The author has made a great many and most varied experiments with a view to test the correctness of these conclusions. It would lead us too far to give these experiments in detail; may it suffice here to state that the general result tended to disprove the second conclusion, viz., that the development of electricity occurs during muscular contraction.

In the course of his statements on this subject, the author mentions that the results of his latest experiments have convinced him that the muscular current is more energetic than the current proper.

The author then proceeds to give a detailed exposition of the numerous studies which he has recently made on the phenomenon of induced contraction. From the results of his experiments on this subject, he draws the conclusion that induced contractions are excited only by muscles in a state of contraction.

He endeavoured, moreover, to excite induced contractions by means of induced contractions; in other words, to call forth induced contractions of the second order, third order, &c. &c. For this purpose he placed the nerve of a galvanoscopic frog's leg upon the thighs of a frog disposed in the usual manner; upon the muscles of the galvanoscopic leg he placed the nerve of another galvanoscopic leg, and so forth. He then placed the whole apparatus upon turpentine. Upon exciting, subsequently, contractions in the frog by applying the electric current to the lumbar plexus, he saw invariably two, and frequently even three, of the galvanoscopic frogs contract simultaneously, and nearly with the same force; but the fourth never exhibited the slightest signs of contraction. We may accordingly assume the existence of induced contractions of the first, second, and third order.

It has already been stated that the interposition of a gold leaf (such as is used for gilding), between the nerve of the galvanoscopic frog and the muscular surface, where the inducing contraction is developed, prevents the manifestation of the induced contraction—that is, if the muscular surface is completely covered with the gold leaf—which is no longer the case after one or two contractions, by which the metallic leaf is rent. It has likewise been stated that the interposition of a sheet of glazed paper has the same effect,

whilst that of bibulous paper imbibed with water or a serous fluid, which moistens the surface of the muscle, does not prevent induced contractions in the galvanoscopic frog. Our knowledge regarding the influence of this interposition of foreign substances was confined till lately to the observation of these three facts. The author has, however, recently tried the interposition of a number of liquids, such as pure water, slightly acidulated water, weak saline solutions, serum, olive-oil, diluted alcohol, various varnishes, and essence of turpentine. He found that the interposition of these liquids does not interfere with the manifestation of induced contractions.

Considering the low conducting power of some of these fluids (oil, essence of turpentine, varnish), we have reason to infer from this result that induced contractions are not destroyed by the interposition of insulating substances.

The author convinced himself that neither the current proper, nor the muscular current, is transmitted across even a very thin layer of these liquids. When a galvanoscopic frog is seized with the hand, and placed in contact with a moistened paper in communication with the ground, contractions are produced. The same phenomenon is observed when the muscles of a frog or other animal, placed in communication with the ground, are touched with the nerve of the galvanoscopic frog. In these cases it is invariably the current proper that circulates through the experimentalist, the ground, the body touched, and the frog; but if the nerve of the latter be previously immersed in oil, essence of turpentine, or varnish, the slight layer of these liquids which continues to adhere to it will suffice to interrupt the circulation of the current proper.

There is, accordingly, no doubt that, as the induced contraction is propagated across an interposed layer of liquids of low conducting power, this contraction cannot be attributed to an electric current which, originating in the muscle in contraction, might be supposed to spread through the nerve of the galvanoscopic frog.

To obtain a positive conviction regarding the propagation of the induced contraction across interposed substances of low conducting power, the author tried the interposition of a still worse conductor than any of the above-enumerated fluids, viz., nearly solid Venetian turpentine, rendered more or less liquid by the adjunction of a small quantity of essence of turpentine. He varnished the thighs of a frog with this mixture, and endured with it also the nerve of a galvanoscopic frog. He found that the induced contractions persist to manifest themselves, notwithstanding the interposition of this non-conductor.

That the mixture used may really be looked upon as a non-conductor, the author has demonstrated experimentally:—He applied one of the poles of a pile to the insulating layer (taking care, of course, not to penetrate to the muscular surface), and touched with the other pole the leg of the galvanoscopic frog: no contractions were observed. These experiments prove, evidently, that induced contraction is propagated through an insulating layer, capable to interrupt not only the current proper and muscular current, but also the current of the pile, which excites the inducing contraction.

If the insulating mixture exceeds certain limits of solidity, or, in other words, does not possess the requisite degree of fluidity, its interposition prevents the manifestation of induced contractions. It is impossible, however, to fix the proper limits of solidity.

The interposition of solid substances, of whatever nature or thickness, between the nerve of the galvanoscopic frog and the muscular surface, prevents invariably the manifestation of induced contractions.

One of the most curious facts is, that induced contractions are propagated through the skin investing the inducing muscles of the frog. This fact is observed invariably, no matter whether the inducing contraction be excited by

means of the electric current, or by any other stimulus applied to the lumbar plexus of the inducing frog.

(The conclusion of this part we must defer till next week.)

DUMAS ON ORGANIC CHEMISTRY.

No. XXVIII.

(Continued from page 491.)

ON THE NATURE OF THE EGG—(continued).

We concluded our last lecture with a description of the general composition of the egg. Prout has made some experiments with the view of determining the relative weight of the different parts which constitute it; he has proved that this weight is liable to change; still, according to a mean calculation made upon ten eggs, he thinks we may admit the following conclusions:—If the entire egg weigh 100 parts, the weight of the shell and of its membrane will range about 10, that of the white at 60, and, lastly, that of the yolk at about 30.

If eggs be kept in the open air they lose daily, according to Prout, from three to four centigrammes in weight, and, after the lapse of about two years, all the parts which they contained will be found dried up into a solid mass which occupies the small end of the egg. If, while in this state, they be plunged into water, they will absorb a large quantity of it, and, up to a certain point, they will reacquire the properties of fresh eggs; at least they will no longer disengage an odour of sulphuretted hydrogen.

When a fresh egg is boiled in water it loses from two to three per cent. in weight, by yielding to this liquid some of the salts contained in the shell, or even in its interior parts. On evaporating the liquor, it throws down a deposit of carbonate, with a little phosphate, of lime, and retains in solution the soda, as well as the sulphates, chlorides, and phosphates of that base, with some traces of animal matter.

The changes which occur in the egg during incubation have been most attentively studied, as well in relation to the successive evolution of the organs of the embryo, as in regard to the chemical phenomena which accompany them. It has been long known that the weight of the egg, during this process, daily diminishes. According to the experiments of Prout, the egg would thus lose, during the three weeks that incubation lasts, about a sixth of its weight, that is to say, eight times as much as it would lose, during the same space of time, under ordinary circumstances. This diminution is due in part to the water which evaporates through the pores of the shell, and partly, also, to a true respiration, of which the effect is to transform into water and carbonic acid a portion of the organic elements of the egg. This respiration of the egg, long since known and clearly pointed out by ancient observers, has been well established by the experiments of MM. Baudrimont and Martin Saint-Ange. These observers caused some eggs to be hatched in a hermetically closed space, of which they raised the temperature by artificial means. A particular arrangement of apparatus, similar to that employed for ascertaining the proportion of gases in the blood, further allowed of their constantly renewing the atmosphere which surrounded the eggs. The internal air, being slowly aspired, yielded to the condensing apparatus all the water and the carbonic acid with which it was charged by its contact with the eggs, and it thus became replaced by pure air, deprived of watery vapour and carbonic acid. But, comparing the loss experienced by the eggs with the augmentation in weight of the condensing apparatus, MM. Baudrimont and Martin Saint-Ange have remarked that these two quantities were far from corresponding, and that the weight of the condensed products sensibly exceeded that which expressed the loss experienced by the eggs. This excess they attributed, with reason, to the oxygen absorbed during the course of incubation. Annexed are

the calculations which they made on this point, from an experiment of three days' duration:—

Water condensed	5.1960
Carbonic acid formed	0.7840
	5.9790
Loss in weight experienced by the eggs ..	4.9450

Excess of products collected over the loss 1.0340

We may then regard the phenomenon of respiration in the egg as a well-established fact. It is indeed a necessary function, inasmuch as *hæmatosis* or sanguification is accomplished in the young bird in a direct manner, whilst in the fœtus of the mammiferæ it takes place through the medium of the maternal blood.

The changes which supervene in the composition of the constituent parts of the egg, during the course of incubation, and which are probably in some measure dependent on that absorption of oxygen of which we have been speaking, are manifest and very important; but, unfortunately, it is a matter of difficulty to trace these alterations, and more especially to explain them. All that we know upon this point may be summed up in the data, drawn from the analyses of Prout, although these themselves may now be regarded as of somewhat ancient date.

At the end of the first week, the egg has lost five per cent. in weight; the white has become more liquid, and coagulates, like sour milk, in clots, which contain a yellowish oil, soluble in alcohol. Prout considers this white as a modification of ordinary albumen. As to the yolk, it has become specifically lighter than the white; consequently, it will be found against the upper part of the shell, imbibing, so to speak, from this source the oxygen necessary to the development of the germ. There is further established, between the white and the yolk, an exchange of principles. The salts of the white pass into the yolk, whilst the latter, still preserving the phosphorus necessary to the development of the osseous system of the young bird, loses a part of its oil. The composition of the gas, which fills the internal chamber of the egg, has moreover changed; it now holds but about 15 per cent. of oxygen in the place of 21.

An egg, after a week's incubation, contains, in 1000 parts:—

Albumen, unaltered	236.8
Albumen, modified	179.8
Amniotic liquid, membranes, and vessels ..	97.0
Embryo	22.0
Yolk	301.3
Shell and loss	171.1

The yolk yields, by incineration, 0.6 of chlorine, and 0.8 of an alkaline residue.

At the end of the second week, the loss in weight of the egg is raised to 13 per cent.; the embryo has already acquired a considerable size, and appears to be developed at the expense of the white, which has diminished in an equal proportion; the albumen is more concentrated, and becomes harder by boiling; the yolk, on the contrary, has regained its original density and volume, but it has already lost a great part of its phosphorus, which has been consumed in the formation of the bones of the young bird. The egg now contains:—

Albumen, unaltered	175.5
Amniotic liquid, membranes, &c. ..	273.5
Embryo	70.0
Yolk	250.7
Shell and loss	230.3

On the seventeenth day, the incinerated yolk and amniotic liquid yielded—

	Yolk.	Amniotic liquid.
Sulphuric acid	0.10	0.34
Phosphoric acid	2.50	1.70
Chlorine	0.50	0.68
Potass and soda (partly in the state of carbonates) ..	0.56	2.40
Lime and magnesia	0.75	1.19

The incubation is terminated at the end of the third week; the egg has now lost 16 per cent. of its weight; the white has almost entirely disap-

peared, and the yolk, being greatly diminished, is enclosed in the abdomen of the young bird. The egg then presents the following composition:

Albumen and membranes	29.5
Embryo	555.1

Yolk 167.7
Shell and loss 247.7
The following table gives the result of the incineration of two fully-hatched eggs, the weight of each being set down at 1000:—

Parts of the Egg.	FIRST EGG.						SECOND EGG.					
	Lime and mag- nesia, partly in the state of carbonates.			Soda and soda, partly in the state of carbo- nates.			Lime and mag- nesia, partly in the state of carbonates.			Soda and soda, partly in the state of carbo- nates.		
Remainder of white and mem- branes	0.04	0.12	0.09	0.23	0.12	0.03	0.13	0.09	0.25	0.12	0.03	0.10
The animal	0.44	3.02	0.55	2.28	2.58	0.21	2.71	0.68	2.12	2.60	0.21	2.71
The yolk	0.04	1.06	0.03	0.06	1.26	0.02	1.23	0.06	0.03	1.10	0.02	1.23
Total	0.52	4.20	0.67	2.55	3.96	0.26	4.07	0.83	2.40	3.82	0.26	4.07
Total of the same substances in the fresh egg..	0.60	4.01	1.33	3.42	0.98	0.37	4.48	1.31	3.23	0.99	0.37	4.48

We may readily see, from an inspection of the foregoing table, that the chlorides and the free alkali have diminished during incubation, whilst, on the other hand, the alkaline salts have augmented in a large proportion. It is, moreover, evident that the shell itself furnishes the earthy materials which enter into the egg, for it becomes thinner and more fragile after incubation.

SEMINAL LIQUOR.

The spermatie fluid of animals is a whitish or rather yellowish-looking liquid, which is composed of a species of serum, of spermatie animalcula, and of granules or globules. The animalcula, which form its chief characteristic, are furnished by the testicle. The spermatie animalcula, which were discovered by Hartzeuker, and described for the first time by Lecuwenhoek, vary in their form and size, among the different animals of a given class or genus, and even in one species as distinguished from another.

If the spermatie fluid of man be examined by the microscope, we find it to be constituted of a transparent liquid in which these animalcula, which in their form are not unlike the tadpole of the frog, are seen to move about with very great rapidity. These little beings have a vitality altogether independent of the animal to which they belong; at least, they preserve their spontaneous movements long after the seminal liquor has been excreted. They may, however, be killed by several methods: the electric spark destroys them; but they resist the action of the pile. Strychnine, prussic acid, the alkalis, and the acids speedily kill them. When introduced into the different fluids of the economy, as the blood, the milk, the liquors of the uterus, &c., they continue to live. They also exist for a considerable length of time in the urine of the animal which has accreted them, but they speedily perish in that of any other. They may live in water.

In their isolated state, they offer the physical characters of fibrine, and obviously present the same chemical properties.

Besides the animalcula, the semen contains some slight granular globules, and particles of epithelium; these globules have been regarded as imperfect, or non-developed, animalcula. The experiments hitherto performed would tend to prove, that it is in the animalcula alone that the fecundating power of the sperm resides. At least, in the experiments on artificial fecundation of the spawn of the frog, this remarkable result has been deduced: that it is the insoluble portion of the semen which fecundates. In fact, the spermatie liquor, when diluted with water, is partially dissolved: and on straining this liquid through double filters, we may convince ourselves that the liquor which passes through cannot impregnate, whilst that part which remains on the paper possesses a fecundating influence.

The spermatie liquor is a viscous, alkaline, and semi-transparent fluid, sometimes presenting a yellowish colour; it possesses a peculiar odour, very similar to that of the pollen of certain plants. It partially loses its viscosity and odour, if collected after several ejaculations; its colour in this case is always white. The odour of the spermatie liquor disappears by desiccation; but it is manifested anew on rendering it moist. According to M. Orfila, it may be recognised by this character, even after an interval of six months; thus, linen which has been stained with seminal fluid, on being moistened with a little water and distilled in a water-bath, disengages a liquor which possesses a spermatie odour.

If, after emission, it be allowed to rest, it loses its viscosity, becomes limpid, and is capable of admixture with water; but, if projected into this liquid at the moment of emission, it sinks to the bottom, and is divided by agitation into filaments.

It would appear, from the foregoing, that, at the moment of emission, the organic matter of the seminal fluid is in a distended state, but not dissolved, and that it becomes liquid and soluble only after a certain lapse of time. The solution which is thus formed is not coagulated by heat. The animalcula appear to be independent of this modification of the spermatie fluid—a modification which is most probably necessary, in the first place, for favouring its sojourn or transportation into the female organs, and, subsequently, for facilitating its absorption by the ovules which it is destined to fecundate.

If the seminal liquor be evaporated, it becomes covered with an organic pellicle, in which we find small grains composed, according to Vauquelin, of phosphate of lime. It leaves, on desiccation, a yellowish, transparent residue, amounting to as much as ten per cent in proportion to the weight of the liquor employed. This residue, according to Vauquelin, is composed of:—

Animal matter	6
Phosphate of lime	3
Soda	1
	10

All the acids dissolve the seminal liquor, and the alkalis precipitate these solutions; caustic potash in like manner dissolves it, but the acids do not precipitate it. Chlorine forms with it a coagulum insoluble in water and in the acids.

According to John, the seminal liquor should contain a peculiar mucous matter, some traces of modified albumen, a small quantity of matter soluble in ether, soda, phosphate of lime, some chlorides, sulphur, and an odorous volatile body.

If, at the moment of emission, the spermatie fluid be allowed to fall into alcohol at a specific gravity of 0.833, and provided it be left for a few instants in contact with this liquid, it becomes opaline, and forms a kind of ball or pellet, appearing as if it had escaped in this state from the

vasa deferentia. It by this means loses the property of again becoming liquid. If it be dried, it remains, as before, fibrous, opaque, and of a snowy-white colour. Water gradually softens it, but dissolves only a very minute quantity even by prolonged ebullition. The portion dissolved by water, on being evaporated to dryness, is partly taken up again by this liquid when cold, and partly by the aid of heat; the infusion of gall-nuts precipitates these solutions. The insoluble portion is not dissolved by weak alkaline lees.

Concentrated sulphuric acid dissolves the coagulum formed in alcohol; water precipitates its solution. This precipitate is not dissolved again by hot water.

Cold nitric acid colours it yellow without dissolving it. When hot, it effects its solution; this liquor, also, is precipitated by water.

Acetic acid renders it gelatinous and transparent, and the acidulated mass is dissolved by boiling in water. The solution is not perfectly limpid; it is precipitated by the yellow cyanuret of potassium and iron, but not by carbonate of ammonia or by the sublimate of mercury; the infusion of gall-nuts produces a precipitate, which is thrown down very slowly.

Lastly, this coagulum, formed by alcohol, is dissolved by the aid of heat in a tolerably concentrated liquor of potash; acetic acid does not precipitate this solution.

If the spermatie fluid be projected into water, it sinks to the bottom of the liquid and there coagulates into a fibrous mass; by agitation, this mass is divided into filaments, which, when withdrawn from the water, may be dissolved by acetic acid; this solution is precipitated by the yellow cyanuret. If these filaments be left for some time in the water, they undergo a partial modification—that is to say, they become in part dissolved, leaving, however, a residue of very divided flakes which are slowly deposited. This residue is almost insoluble in acetic acid.

If the aqueous solution be evaporated in a water-bath, it disengages a seminal odour, becomes eventually opaline, and leaves an almost invisible varnish on the glass; this varnish, when moistened with water, becomes opaque, swells up, and detaches itself from the vessel; water dissolves but a very small portion of it. The evaporated solution yields to pure alcohol a small quantity of extractive matter which strongly reddens litmus-paper. Alcohol at 0.833 dissolves another portion of it. Both these solutions give up a substance possessing the properties of animal matter.

The soluble part of the semen, when dried and acted on by alcohol, yields to boiling water a certain quantity of an extractive matter, which colours the solution, and which remains, after evaporation, under the form of a yellowish, transparent, perforated mass, soluble in water. This solution forms, with the neutral acetate of lead, protochloride of tin, nitrate of silver, and infusion of gall-nuts, copious mucous precipitates.

The portion, insoluble in water, is not dissolved by acetic acid, and only partially so by cold dilute liquor of potash.

The potash solution, when neutralized by acetic acid, throws down a precipitate with infusion of gall-nuts; if evaporated, and then acted on by water, it leaves the organic matter behind under the form of a mucilaginous mass.

NAVAL APPOINTMENTS.—Assistant-Surgeons: Edward Adams, to the Victory; R. J. Squire and W. J. Hamilton, to the Caledonia.

APOTHECARIES' HALL.—Gentlemen admitted members August 19: Thomas Hunter, Martin Folkes Bush, Samuel Griffith, and John Simmonds Nedham.

THE BRITISH MUSEUM.—On Tuesday the trustees obtained possession of all the houses required in Great Russell-street for the erection of the east wing of the Museum, including the extensive buildings belonging to the Clerical, Medical, and General Life Assurance Company, clearing the ground entirely to Montague-street, Russell-square.

ORIGINAL CONTRIBUTIONS.

CASE OF DEATH FROM ARSENIC, MEDICINALLY ADMINISTERED IN SMALL, BUT LONG - CONTINUED, DOSES; IN OTHER WORDS, CASE OF SLOW POISONING BY ARSENIC.

By GEORGE S. HOOPER, M.D., Jersey.

2. CASE OF CONGENITAL IMPERFORATION OF THE VAGINA.

My attendance was one day required for a young girl who was labouring under intense pain across the hypogastric region and in the loins, accompanied with irresistible and almost constant desire to relieve the urinary bladder. On my arrival I found her enjoying an interval of comparative ease, sitting listlessly on a sofa, with the heavy florid countenance of a plethoric and hysterical girl. She was seventeen, robust, and bore all the external signs of puberty; but, as the catamenia had not as yet made their first appearance, the present indisposition seemed naturally referrible to an approaching change. The severity of the symptoms, however, indicating greater disturbance than commonly attends that important revolution in the female system, some saline medicine was ordered, with a view to reduce the plethora. On the following day I received a very urgent summons to attend immediately, as something most extraordinary had taken place in the condition of my patient.

It would be difficult to describe the air of consternation with which the mother received me; she was actually breathless with agitation, at the same time that a sort of mysterious look showed that she was prepared to hear some dreadful piece of information from me. As to the daughter, she lay on her back apparently exhausted with pain, and quite as heedless of exposure as if she had been in the last stage of a tedious and difficult labour. At intervals she groaned and strained as if in the act of parturition. On examination I found in the vulva a livid, fluctuating tumour, the size of a goose's egg. The nymphs were so effaced, the orifice of the urethra so perfectly closed, and the clitoris so completely out of view, that the pudenda seemed to possess no part of their natural conformation, save the mons veneris and labia. It was impossible not to feel a little startled by phenomena so novel, particularly as the history of the patient's previous symptoms had been only imperfectly made known to me, she being of a shy and taciturn disposition. Having soon ascertained that the case was one of retention of menses from imperforation of the vagina, I opened the tumour by a transverse incision, through which slowly escaped a thick inodorous liquid, resembling port-wine lees in colour and consistency. This immediate discharge amounted to above a quart, and it is hardly necessary to add that the relief which the sufferer experienced was very great, and the astonishment of the bystanders no less so. That this menstrual fluid had for a considerable time been submitted to the action of the absorbents was evident from the degree of density which it had acquired. Its large quantity likewise showed that it was the accumulation of several effusions, probably periodical, and attended with the usual general phenomena of menstruation: for the latter function established itself with perfect regularity from the moment the mechanical obstacle to its external manifestation was removed. On the day following the operation I examined the vagina with the index finger. It was collapsed, flaccid, with numerous large loose folds, representing an empty sac rather than a canal; its rugæ felt harder, and its structure altogether tougher, than natural. The neck and orifice of the uterus had undergone no perceptible change, feeling precisely the same as they do before any impregnation has taken place; consequently, the vagina had been the sole receptacle of the accumulated fluid, and the degree of distention it had suffered was proportioned to its large quantity. A stout tent of lint was passed through the new opening, on the with-

drawing of which, for three days there escaped the same sort of liquid. Later, this carried along with it masses of thick mucus, till, becoming gradually thinner and less coloured, it ceased to flow at the expiration of the eighth day from the operation. There only remained to render the artificial opening permanent, and this was effected by means of a skein of thread drawn from old linen, large enough to be tightly fixed in the wound. At each dressing, which was soon entrusted to the patient's mother, two or three threads more were added, until the wound being healed the orifice had acquired the ordinary size. The menses have since returned periodically, and without any particular inconvenience.

REMARKS.

The foregoing case has been deemed worthy of being laid before the medical public, not because similar ones are few in the annals of our science, but on account of their being relatively uncommon, and not coming under the observation of most practitioners. It cannot, I believe, be altogether useless to refresh the memories of medical men respecting diseases which are of rare occurrence in practice. Not thinking of the real cause of retention of the menses in a case of this nature, and principally struck by the stout, healthy appearance of the patient, a medical man might, by an unguarded expression, place an innocent girl in the most painful of situations. Retention of menses from this cause has sometimes been mistaken for pregnancy, from the distention of the womb which followed a considerable accumulation of the fluid in its cavity; and the tumour, which I have described as presenting at the vulva when the expulsive efforts commenced, has been taken for the membranes of the ovum. Smellie himself once fell into the latter error, as he candidly acknowledged. Such mistakes, though soon rectified, may not, however, always be harmless or unimportant. On the contrary, examples are related by authors, of girls having, under similar circumstances, been ignominiously treated as if pregnant and attempting to conceal their shame, when they were only indignantly repelling a false accusation. Is it enough that the event should afterwards wipe off the aspersion? No!—for it too often happens, unfortunately, that when the fair fame of woman has been exposed to the pestilential breath of slander, the explanation which proves her innocence is received by ignorance and malice only as a specious story invented for the purpose of re-establishing her in the good opinion of the world. It is, then, of great importance that such mistakes should not be committed, and that the profession at large should be put on their guard against them whenever an opportunity presents itself. In this manner the experience of each practitioner spreads through the whole body of the profession, medical men become more generally enlightened, and the benefits accruing to mankind from our noble art may be indefinitely extended. Now-a-days a medical man, however remote his sphere of action may be from the great fountain-heads of knowledge, need never be below its latest level; nor can his youthful competitors, as formerly, pretend to superiority over him on the score of more modern education, and the great advances of science since his time.

The quantity of menstrual fluid retained in similar cases, related by different authors, is stated to have been far more considerable, being partly contained in the uterus, which rose above the pubis, and formed a tumour as in pregnancy. How that organ, in the virgin state, could suffer that degree of expansion from that cause is somewhat difficult to understand, when we reflect that here the dilatation would be purely passive, and not the result of modified vital action, as in the gravid state. Would not one expect rather that the vagina would continue to yield to the pressure of the fluid, and, in the progress of its expansion, would throw the uterus aside to occupy its place above the brim of the pelvis? At all events, in the present case, the quantity of accumulated liquid was already considerable, and yet the uterus had undergone no change. In fact, if we view menstruation as a secretion, we

will hardly be able to conceive how that secretion should continue to repeat itself naturally if the organ of it was undergoing any such mechanical change. As to the sort of discharge which came off after the operation, it clearly was not pure blood, "*sicut a victima*," as Hippocrates, and many after him, have held the menstrual fluid to be. Blood effused in a cavity, or in the cellular membrane, and there retained for a certain time, exposed to the action of the absorbents, becomes changed into dark coagula, and loses more or less of its fluidity, unless altered by the admixture of some other liquid. Here, on the contrary, the liquid was only thickened, and its colour, though darker from that cause, was by no means approaching to black, as we find real blood under the same circumstances. These considerations, I believe, tend to support the views of those physiologists who look upon menstruation not as a mere exudation of blood, but rather as a secretion approaching to blood in its sensible qualities, but never identical with it in the healthy state of the function.

FOREIGN PRACTICE.

Reported for the MEDICAL TIMES by ALFRED MARKWICK, Esq., Surgeon to the Western German Dispensary, and formerly Externe to the Veneral Hospital, Paris, &c.

A NEW TREATMENT OF ABSCESS BY CONGESTION.—PRACTICAL REMARKS BY M. ROBERT.

A case of this nature occurred some time ago in the practice of M. Robert. The patient was a female, and the abscess was situated on the lower part of the back. It had been opened about eighteen months previously, by a practitioner in town, but a fresh formation of matter had taken place. In lecturing on this case, M. Robert mooted a very important question, viz.—how these abscesses—considered separately and without any reference to the cause by which they are produced and entertained, and which, in the majority of cases, is an organic alteration of the osseous tissue—ought to be treated.

It is well known, said he, that if left to themselves they eventually burst. The external air penetrates through the opening thus formed into the cavity of the abscess, and alters the nature of the pus, thereby giving rise to very severe symptoms, which endanger the life of the patient; thus diarrhoea, hectic fever, and frequently phenomena of a truly typhoid character, and of purulent absorption, make their appearance, and carry off the patient. So true is this that surgeons have at all times endeavoured to prevent these sad results, by giving issue to the suppuration in various ways.

Some have adopted the plan of opening these abscesses by means of a narrow-bladed bistoury, and allowing a portion of the matter to escape; then closing the opening, and subsequently, when fresh matter has formed, resorting to the same proceeding again. Boyer and Dupuytren pursued this kind of treatment. This plan was ineffectual, for sooner or later the cyst became inflamed, the pus vitiated in its character, and it was necessary to open the tumour largely; and yet, notwithstanding this, the patients generally died. In fact, so universally was this the case, that Dupuytren, towards the latter part of his life, allowed these abscesses to take their course. Lisfranc attributed the accidents above mentioned to inflammation of the cyst; therefore, in order to prevent them, he opened it at once largely, emptied it of its purulent contents, and then covered it with leeches. This method was followed by some success, and I have myself employed it with advantage; but I have also seen very fatal results to arise from it; and, as the patients in whom this kind of abscess is met with are generally of a lymphatic habit, and bear the loss of blood badly, I have abandoned it.

Recamier proposed to empty them by a small opening, and to protect them from the contact of air by keeping them constantly filled with an emollient liquid, which was introduced into their cavity through a gum-elastic canula. I have only once had recourse to this method;

still the pus became putrid, and the patient sank from the abundance of the discharge, and from purulent absorption. Lastly, M. Guérin recommends the pus to be evacuated by means of subcutaneous punctures, which are repeated as soon as the cavity of the abscess has become filled with matter. There can be no doubt that this mode of operating prevents the fetidity of the pus and its consequences better than all the others, yet I have known unfavourable results to follow after one or more punctures, in cases where the opening made by the trocar had not healed by the first intention; besides, like the other proceedings we have mentioned, it is, properly speaking, but a palliative treatment.

If we study the progress of nature in these instances, we find that in fortunate cases (independent of those very rare ones in which, from the flow of pus becoming arrested, the abscess remains stationary for an indefinite period, becomes partially absorbed, and at length becomes reduced to a compact mass like adipocere); the abscess bursts by a small opening which becomes alternately closed and opened, and eventually converted into a fistula, which continues until the diseased state of the bone, by which the suppuration is occasioned, is cured. This opening gives passage to the pus, and the particles of bone it carries with it. The fistulae are, as may be imagined, of very long and often of indefinite duration.

It must be acknowledged, that when art has not been able to stop the progress of these abscesses, nor prevent their bursting, this mode of termination is the only one the surgeon can desire.

The treatment, therefore, may be said to consist in establishing a fistula, and preventing the dangers consequent on the opening of the cyst.

In reflecting on this question it appeared to me that we ought—

1. To penetrate into the cavity of the abscess by a narrow opening made in an oblique direction, and through which the atmospheric air—the cause of the inflammation of the cyst—cannot possibly enter.

2. To prevent the closing of the wound by keeping in it a foreign body that is but little susceptible of exciting irritation, and merely occasion the development of plastic inflammation.

Metallic bodies, we know, do not give rise to suppuration in the tissues through which they pass; indeed, we find pins, needles, bullets, and other similar bodies remain there for an indefinite period, by becoming surrounded at first with an albuminous pellicle, and afterwards with a fibrous one by which they are encysted.

On these grounds, therefore, I have adopted the following proceeding:—

I introduce a very fine curved trocar into the abscess on one side, and when it has reached its cavity (which we can readily detect) I draw the trocar back into its canula, and then push this towards the opposite side of the abscess; when there I press upon the trocar, so that it penetrates the parietes of the cyst from within outwards, carrying with it the canula, which is thus made to pass twice through the walls of the abscess.

This canula enables me to introduce a leaden wire, which alone remains in the cavity of the abscess, its escape being prevented by twisting its ends together.

It will be seen that by this method—

1. That the external air cannot come in contact with the interior of the cyst, owing to the opening being occupied and closed by the metallic wire.

2. That the pus can only escape slowly and, as it were, by a sort of filtration between the foreign body and the wound.

3. That the foreign body itself, being but little irritating, tends to excite in the soft parts a very circumscribed and not suppurating inflammation.

The patient upon whom I have practised this plan had a rather large dorsal abscess, due in all probability to some alteration of the posterior surface of the third rib near its vertebral articulation.

This abscess was opened on the 17th of June, 1847, according to the method above described. The patient complained of some pain occasioned by the presence of the metallic wire, but up to to-day, the 28th—that is, eleven days after the operation—no febrile symptoms have become developed. A small quantity of pus makes its escape every day round the wires, and is at present perfectly inodorous. The walls of the abscess are soft and indolent; there is merely a small red areola round the wires. If, as we hope, no fresh symptoms make their appearance, we shall allow the metallic wire *in situ* until the punctures appear sufficiently indurated to become converted into fistulae. — *Gaz. des Hôpitaux*.

19, Langham-place.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of Aug. 16; M. BRONGNIART in the Chair.

COMPOSITION OF THE BLOOD IN SCURVY.—M. Maréchal de Calvi, in an essay upon this subject, acknowledged the truth of Professor Andral's observation, that the quantity of fibrin might not be diminished in the blood of scorbutic patients, but accounted for the fact by the inflammatory condition generated in the circulating fluid by the efforts necessary for the resorption of extravasated blood. The singular coincidence of the diminution of albumen and of globulin, with the absence of dropsical effusion or of murmurs in the heart and arteries, M. Maréchal explained by the difference which must exist between diminution of the power of creating albumen in the blood, and genuine decrease or destruction of this component principle.

TREATMENT OF CANCER.—M. Riviérolle read a paper on the use of caustics for the treatment of cancer. In a general manner Dr. Riviérolle stated that caustics were preferable to the removal of these tumours with the knife. Concentrated nitric acid had yielded him in his practice most advantageous results. Poured over a pledget of lint, it constituted with the latter a semi-solid cake, which moulded itself to the shape of subjacent parts, and effectually prevented hemorrhage. It was particularly in fungous tumours disposed to this accident that M. Riviérolle had found nitric acid useful as a local application. M. Riviérolle also in many instances employed alum for the purpose of arresting the progress of hospital gangrene.

SPONTANEOUS DISLOCATION OF THE KNEE.—M. Palasciano forwarded a communication, in which he endeavoured to establish—first, that the muscle known as “tensor vaginæ femoris” did not deserve that name, but, being inserted by long tendinous fibres to the external condyle of the tibia, its use was to rotate the leg outwards, and to abduct the knee when it is bent. Starting from these anatomical data, M. Palasciano observed that the spontaneous dislocation of the knee was a complicated affection constituted by the flexion, rotation, and abduction of the knee; displacement of the tibia backwards, of the patella outwards, and often with more or less complete ankylosis. In order to cure this disease, which had hitherto been erroneously considered as irremediable, M. Palasciano proposed the section of the flexor tendons, of that of the rotator externus (tensor v. f.), of the rectus femoris, and vastus externus, also the division of the external lateral ligaments of the joint: preliminary operations which would permit the rupture of the ankylosis and the surgical reduction of the limb to its natural direction.

ACADEMY OF MEDICINE.

Meeting of Aug. 17; M. BÉGIN in the Chair.

DISLOCATION OF THE BONES OF THE PELVIS.

M. Régis reported favourably on a paper by Dr. Murville, military surgeon at Lille, and from this communication we extract the following details of two interesting cases of dislocation of the Pelvis:—

1. An officer, aged thirty-eight, fell from the third story of a house; the thighs were bent and brought towards the abdomen, and the weight of the body bore chiefly upon the tuberosities of the ischia; the result was the forcible separation of the sacrum from each ischium; the sacrum was forced downwards, and protruded considerably under the skin, the ilia being at the same time pushed upwards so as to come into contact with the false ribs; the coccyx was separated into several fragments; excessive pain was felt in the sacro-iliac symphysis; the lower extremities, the bladder, and rectum, were paralysed; the pulse was exceedingly small, &c. Stimulants brought on a speedy reaction, when antiphlogistic measures were adopted, and the pelvis was kept in a state of perfect immobility. No attempts were made at reduction. Not only was life preserved, but at the present day, ten years after the accident, the bladder and rectum are voided at will, and the patient can walk, although with some difficulty. Considerable deformity persists.

2. Col. C., aged fifty-six, during a review, on the 19th of October, 1846, riding an unmanageable horse, pressed him violently between his legs, at the same time that he rose in his stirrups. The animal continuing restive, the rider was thrown upwards, and fell vertically into the saddle in the position we have described. The left side of the soft pelvis was lacerated, the skin not being wounded. A second effort of the horse increased the injury, which extended as high up as the symphysis pubis. This articulation was opened, the internal pillar of the inguinal ring torn, and the patient had the distinct consciousness of these successive divisions of the fibrous tissues. On examination a considerable hernia was found to have taken place in the left inguinal region; in the perineum, which was the seat of intense pain, was also detected a round soft tumour, which yielded to pressure, and which could be reduced with very slight effort. The symphysis pubis was open, and by pressing back the skin with the hand, the distance between the pubis was found to equal two inches in extent. The fibro-cartilage had been torn away from the left ramus, and remained adherent to the right side. The hernia was reduced and the pubes kept united with a tight bandage. The patient got perfectly well, and three months and a half after the occurrence of the accident no trace whatever of its existence could be detected.

LITHOTRITY. — ADJOURNED DEBATE. — M. Civiale read the second part of a paper, the commencement of which we forwarded to the readers of the *Medical Times* in our Parisian correspondence of July 17. M. Civiale stated that Souberbielle had obtained 28 cures out of 39 cases of lithotomy; of 100 patients operated at the Hotel Dieu, 56 only were cured; out of 65 operated at La Charité, 35 died; and of 73 patients on whom lithotomy was performed, from 1836 to 1842, in the hospitals, 25 patients died and 47 were cured: statistical results from which it followed, that the proportion of deaths from lithotomy amounted to more than the third part of the persons operated upon. M. Civiale concluded:—1st. That lithotritry, when properly performed, saved 96 or 98 per cent. of the patients. 2nd. That, when lithotomy was exclusively employed, the mortality was equal to 39 per cent. When applied to children alone, cystotomy was successful in nine cases out of ten; but when applied to adults or to the aged, 50 to 75 per cent. only were benefited.

Meeting adjourned at five o'clock.

DIARRHŒA OF CHILDREN.—The diarrhœa which accompanies or follows the period of weaning is often fatal; it is not only observable in children who are suddenly deprived of the breast, but also in those who are nursed for too long a period. Dr. Weiss, physician to the Children's Hospital in St. Petersburg, advises the exhibition of raw meat in such cases, and asserts that he has from this practice often derived the most signal advantages. The meat should be shaved, or reduced into a pulp, and two table-spoonfuls may be at first given in four

meals.—*Annales de la Société Méd. Chir. de Bruges.*

HOPITAL SAINT LOUIS.

CLINICAL LECTURE BY M. CAZENAVE.—ACNE.

Acne is the result of the more or less complete alteration of that oily substance known under the name of sebaceous matter, and secreted by follicles deeply seated in the texture of the dermis. The eruption of acne is characterized by the appearance of small isolated pustules, more or less hardened at their bases, and occupying the cheeks, nose, forehead, and often the neck and back. According to Galen, acne was due to a thickening of the blood; Cullen looked upon it as a phlegmonous inflammation; Willan and Bateman classed it with tubercles; but Bielt and French pathologists consider it to be a pustular affection. It is easy to discover that the pustules are the first, the primary alteration of the skin, and that the tubercular hardness of their bases is consecutive to their chronic induration. Several varieties of acne may be admitted. Thus in acne simplex, or acne punctata, the disease consists in the accumulation of sebaceous matter in the follicular duct, or in the dilatation of the latter. Acne sebacea is characterized by the increase of follicular secretion, which dries up, becomes hard, forms a crust, and obliterates the orifice of the follicle. If inflammation occupies the sebaceous ducts, or invades the follicles themselves, the two more severe varieties are produced, viz., acne rosacea, or acne indurata.

In acne simplex, small red spots are first observed, which become rapidly pustular and are surrounded by a red areola; no general symptoms accompany the eruption. This form is frequent in young persons verging upon puberty, at the first appearance of the menstrual discharge, and, although not connected with any abdominal complication, it still is very obstinate.

Acne punctata is caused by the accumulation of sebaceous matter in the distended duct: black specks corresponding to the orifice may be seen in the centre of the pustules. This variety of acne seldom exists alone, and is generally complicated by the former.

Acne sebacea occupies almost always the face, and more particularly the nose and the free edge of the eyelids; the sebaceous secretion hardens and forms crusts, which the perspiration separates from the skin, leaving a surface rendered rough by the presence of sebaceous matter distending the ducts. The skin is shining, covered with an abundant oily deposit, and is the seat of slight pruritus. This malady is more commonly observed in the adult than in youth or old age; it is often met with in women who paint their hair or eyebrows.

Acne rosacea is much more serious than other forms already enumerated, both on account of its remarkable obstinacy and of the violent grief which it produces in those who suffer from it. The disease generally begins by some red spots upon the nose, the chin, or cheeks, at first only transitory, and appearing after a heavy meal or even at regular intervals; they are often preceded by inconvenient flushing: the pustules unite, the skin becomes rough, its vascular system is gradually dilated, and the size of the feature often considerably increased. This disease, instead of attacking the entire extent of the nose, may be limited to one of its lobes, and present great resemblance with "noli me tangere."

In acne indurata the inflammation produces often extensive hardening of the skin. It is sometimes met with in the face, and occasionally on the shoulders. When the disease is intense, the face is covered with tubercles of a livid hue, and presents a repulsive appearance.

The diagnosis of acne is not in general difficult to establish. In lichen the eruption is papular, and attended with considerable itching. The squame of ichthyosis are dry, very adhesive, and deeply implanted in the dermis. The scales of pityriasis are furfuraceous. Ecthyma differs from acne by the greater size and by the seat of its pustules, which generally occupy the legs. The peculiar aspect of syphilitic eruptions, their

crenate shape, special colour, and the history of the cases, will prevent the possibility of mistaking them for acne: acne leaves after it small white scars like inverted commas, which always betray its former existence.

Acne does not threaten life, but constitutes, however, on account of its obstinacy to treatment, a serious affliction.

The disease may be referred to the agency of three principal causes: inheritance, gastro-hepatic disturbance, and menstrual irregularity.

Acne simplex may sometimes be cured by emollient lotions, but, in general, stimulating washes are necessary; we recommend the following prescription:—*Rx.* Infusi salviae, 3xij.; liquoris ammoniaci gutt., x. to xl. If a plethoric condition or a derangement of the menstrual function be present, they must, of course, be treated in the most efficient manner possible. In acne punctata alkaline or vapour baths are often useful. Sudorifics and laxatives will be found beneficial in acne sebacea. In acne rosacea the condition of the womb should be carefully ascertained, and if the eruption has appeared to coincide with an arrest of the menstrual function, blood should be removed from the arm, and an issue placed in the thigh. No ointments or greasy substances should be locally applied. Gowland's lotion is often advantageous; the following is its composition:—*Rx.* Hydrargyri bichloridi, gr. ij.; ammoniaci muriatis, gr. ij.; aquae destill., 3xij. *M.* Acne indurata is almost invariably attended with functional disorder: we, therefore, advise the exhibition of carbonate of soda and other alkaline drugs locally. We use several ointments: for instance, *Rx.* Potassii iodidi, 3ss.; ung. hydrarg. fortioris, 3j.; axungie, 3j. *M.* Shower-douches, with simple or alkaline water, are often very advantageous; when the disease is quite chronic the internal exhibition of sulphurous water may be resorted to. Sea-bathing should be recommended in no instance. Lastly, when no indication can be detected upon which to found a rational line of treatment, arsenical medicines, sometimes successful, should also have a trial.

D. McCARTHY, D.M.P.

On the Use of Ether in Surgical Operations.—

Professor James Syme says that the results hitherto obtained have been not at all satisfactory to his mind. In some cases, with apparatus extemporaneously constructed, and afterwards with instruments made more perfectly, the desired insensibility was not produced; in others, prolonged nausea and vomiting; in others, violent convulsive movements were produced; while in several instances death occurred under circumstances that seemed to leave no doubt as to its having been produced by inhalation. Under these circumstances, before abandoning its entire use, Professor Syme resolved to make another series of trials with a very simple apparatus, said to have been very extensively used by the professor of midwifery without producing bad effects. This was merely a flask to hold the ether, poured upon some bibulous material, such as a piece of flannel, with a mouth-piece, and an aperture in the side to admit air. The wide openings, and absence of valves, rendered respiration by this apparatus perfectly free; while there is no risk of the ethereal vapour being allowed to enter the lungs without a safe admixture of atmospheric air. The consequence was that the patients, on the whole, inhaled a smaller quantity, and suffered in a proportionate degree less of the disagreeable effects.

On the Causes of Scorbutus.—Dr. Ritchie concludes, from the facts which have come under his notice, that the following are the causes of this disease:—A want of proportion between the elements in the food of the patients, and those demanded by their organism as omnivorous animals. An habitual and protracted diminution in the supply of many, of nutritive constituents of every sort; the absence from that produced in many more, of the nitrogenous principles of fresh animal food, and the extinction in it, in all, of the albumen, acids, and salts supplied by

succulent vegetables. The coetaneous influences—positive and negative—of other depressing causes, as great physical labour, severe exposure to the weather, previous debility, &c. And under such a disposition of the circumstances of the investigation, it would be improper to seek the causes of the epidemic in the unknown and impalpable obscurities of an aerial constitution. Errors in diet, and the want, in particular, of proper vegetable food, were the true exciting causes; while cold and other debilitating agents operated often as the predisposing causes of the disease.

Proximate Nature of Scurvy.—"The essential principle in the proximate nature of this malady," remarks Dr. Ritchie, "appeared to be diminished vital power; the immediate cause of which was probably the deterioration, as its earliest general effects were the irregular distribution and, also, the transudation of the blood, or of either its serum or its globules. The external phenomena, again, to which these gave rise were general tegumentary anæmia, œdema, sometimes anasarca, and local congestion; while the character of these latter varied according to different accidental circumstances. Thus, parts the vitality of which is relatively low—as the adjacency of old wounds, and the skin on the inferior extremities—or which are exposed from position or function to pressure, or other similar influence, as the soft parts of the extremities, the gums, the lungs, or bowels, were the first to manifest the disposition to hemorrhage, and also, on the exposure of the patient to cold, to assume a cachectic type of inflammation. This, again, though in its genuine nature unhealthy, exhibited various specialities, according to the tissues in which it was situated. Thus, when it affected serous and fibrous structures, a low kind of rheumatic inflammation was set up, fibrine and serum were effused, and, according to the locality involved, there was pleuritic effusion and synovitis, deep-seated neuralgic pains in the bones, or distended and impacted fascia of some of the limbs. When the superficial cellular texture, again, was its site, the inflammation assumed a low form of the suppurative, and gave rise to furunculi; while, when it laid hold on the mucous tissue, an unhealthy erysipelatous action was induced, by which sometimes the epithelium or cuticle might be seen elevated by bloody serum into blebs, or the pilous or mucous follicles be converted into papules, sometimes scarlet, at others purple coloured; and often, if on the cutis, passing into desquamation, or, when situated in the mouth, throat, or intestines, running into ulceration. Chemical and microscopical examinations of the blood showed a diminution of the red corpuscles and of the fibrine, with augmentation of the water, and often of the colouring matter of the serum."

New Muscle in the Eye.—Dr. Brücke states that he has discovered a new muscle in the human eye. It consists in the grey ring which is found in front of and in the neighbourhood of the iris, on the external surface of the choroid, and which has been usually known under the name of the ciliary circle. It is called by the discoverer the expansor muscle of the choroid, and appears to have the same power as that of the iris.

Alkaline Urine in Health.—Dr. Adolph Krukenberg, of Brunswick, quoted in the *Monthly Journal*, says that the fact, first promulgated by Wöhler, that the internal use of salts of vegetable acids, and fruits containing them, causes the urine to be secreted alkaline, has been too much neglected by succeeding physiologists and pathologists. Dr. Krukenberg found that a much smaller quantity of fruit was necessary for the production of this phenomenon than has hitherto been supposed, namely, two to four ounces of apple pulp, or twelve plums weighing, without the stones, scarcely one ounce and a half, sufficed to make the urine alkaline and hazy from phosphates, or, if clear on secretion, heat caused their deposition; the addition of a little hydrochloric acid caused an effervescence like champagne. Too much liquid, a bladder already

filled with acid urine, or a disproportionate allowance of flesh, interfered with the success of the experiment. In the simple chronic nephritis of Rayer, the chief symptom is the alkalinity of the urine; and some of the cases recovered so quickly as to justify a doubt as to the correctness of the diagnosis; although he inculcates careful dietetic treatment, it is evident that the someiotic influence of fruit in small quantities was unknown to him. In several of his cases the alkalinity of the urine seemed to depend on purulent admixture, and consequent rapid putrefaction; and once it seemed to be kept up, if not produced, by the use of an alkaline saline water. The alkalinity of the urine has also been used by Prout as a diagnostic sign of certain spinal affections; these he divides into two great classes:—1. Those arising from depressing emotions and weakening influences; and in these he recommends the use of fruits, and fluids containing malic acid, as cider and perry; to these, and not to any disease, Dr. Krukenberg refers the alkalinity of the urine. 2. Injuries of the spine; neither Rayer nor Dr. Krukenberg, however, have ever been able to discover the urine alkaline from this accident, unless there were some existing or consecutive affection of the mucous membrane of the urinary passages, producing purulent admixture, hastening thereby the putrefactive changes in the urine. Prout also mentions that although alkaline urine, by copious secretion, be clear and bright, yet boiling causes it to deposit a phosphatic sediment, which falls without any such previous process if the secretion be more sparing; the phosphates separate before the boiling point, and from their great specific gravity fall rapidly, and may thereby, as well as by their solubility in acids, be distinguished from the albumen found in Bright's disease.

Cauterization of Vesico-Vaginal Fistula with Creasote.—Professor Emmert, of Bern, having a case of this disease subsequent to artificial labour, and which had been treated seventeen times with *Lapis infernalis* unsuccessfully, proceeded to remove the gangrenous scab produced by the last cauterization, and then touched the fistular opening extensively with a pencil-brush immersed in creasote, which produced the most beneficial results. The new scab was so firm as to enable the patient to retain her urine the whole day, and to micturate without becoming moist. The detachment also occurred much later than after the application of other caustics, and, when effected, the urine flowed in far less quantity from the somewhat diminished fistula. A second application, six days afterwards, induced a perfect cure, and no urine has passed from the fistula during two months which has since elapsed. A fortnight after the last cauterization the fistula was found perfectly cicatrized, its previous existence being marked only by a bluish-red streak two lines in length. Creasote is considered, therefore, to be superior to either the nitrate of silver or the concentrated acids, the one being too feeble and the other too energetic in their action.

Nævus Maternus Lipomatodes.—Dr. Hollstein, of Furtth, mentions the case of a boy, two years and a half old, whose back was covered with hairs an inch long, which, on the left side, reached to about the middle of the abdomen. More or less there was the same abnormal development on the upper part of the left thigh, the lower and anterior surface of the right thigh, and the right scromion. The nates were covered with two darkish-brown sacks, which hung down over the femoral fold, and in the left inguinal region was an isolated fatty prominence five inches long. The skin covering the swellings was dense to the feel, smooth, with fissures here and there, and having on its surface several darkish-blue or brown naevi, some with and others without hair. From the growth on the nates there ran a tuft of close hairs over the spinous processes of the vertebrae up to the occiput. The child resembled an ape posteriorly. Three months prior to death a fluctuating blue-coloured growth appeared below the left shoulder, which increased to the

size of a child's head, and yielded, on incision, a bloody, glutinous fluid. An encephaloid-like mass, covered with coagula of blood, occupied the base of the swelling, and the patient eventually died. At the autopsy the lipomatous growth on the nates, though diminished from its original size, weighed five pounds. It consisted of a fibro-serous sack, partially filled with isolated fat masses. Under the microscope, cellular filaments and free non-crystallized fat were everywhere seen. The coloured spots contained a quantity of granular pigment, both free and enclosed within cells, conjoined with numerous epithelial cells. The axillary growth exhibited, in addition, oblong and caudate cells, so as to justify the diagnosis of encephaloid.

Solid Bodies in Synovial Cavities.—Dr. Bidder opened a long-standing swelling of the knee-joint, from which escaped a quantity of granular matter. The grains were of a uniform size, $1\frac{1}{2}$ '' long, $\frac{1}{4}$ '' broad, $\frac{1}{4}$ '' thick—regular, flat, oval, clumped together in masses of variable size by a glutinous transparent fluid, present in but a very small quantity; they were highly elastic, and presented no trace of a pedicle; their cut surface seemed homogeneous to the naked eye, and presented no trace of organization under the microscope; and a chemical examination showed them to be composed of albumen. The hypothesis offered in explanation of their mode of origin is, that in certain cases an increased flow of blood, and consequently secretion of synovia, may force off the epithelium cells; that these subsequently increase, partly by endosmosis, partly by precipitation on their external walls; the peculiar life of the cell-wall in certain cases altering the contents both with respect to colour and consistency, no membrane being perceptible under the microscope, may proceed from its stretched and thinned condition, from its being originally structureless, or from its homologation with its contents. The bodies examined consisted almost entirely of albumen, easily obtained from the synovia; their uniform size likewise presupposed their origin to have been from similar forms, endowed with similar capacities for life, conditions fulfilled by the epithelium cells.

Apoplexy of the Larynx.—A patient was admitted into the Zurich Hospital, labouring under general symptoms of the action of mercury, and produced by friction with mercurial ointment, with the intention of ridding himself of lice. The symptoms were partially relieved by gargles and the use of hydriodate of potass. Two days after admission, having left the room but lightly clothed, the patient was seized with a violent dry cough of a croupy sound; the voice became hoarse and almost extinct; breathing whistly, short, and anxious; eyes protruded; pulse frequent, oppressed; face livid and covered with a cold sweat. Auscultation showed nothing abnormal; water was swallowed easily; remedies proved useless, and in the evening he died. The autopsy showed on the internal surface of the larynx, beneath the right ventricle, a darkish-red bloody coagulum, extending downwards a quarter of an inch and 1 to 3'' deep, lying directly under the mucous membrane, which was somewhat thickened; immediately beneath the left ventricle existed a less extensive sugillation. The mucous membrane was also softened and thickened; that of the trachea and alimentary canal studded with ecchymotic spots. Here the proximate cause of the fatal effusion was undoubtedly the fluidity of the blood, caused by the absorption of an unknown quantity of mercury. The cough with which the patient was affected determined the seat of the effusion. Cases of sudden death during mercurial inunction have been generally ascribed to a carditis. Apoplexy of the larynx causing death has been rarely noticed.

Loss of Voice Cured on the Occurrence of Hemoptysis.—A female, nineteen years of age, was lightened, while menstruating, by a horse running away, and at the same time caught cold, when she became affected with complete aphonia. There was no hoarseness, pain, or cough; the tongue was clean, though the patient complained of a putrid taste in her mouth. Sal ammoniac

and tartrate of antimony were presented without success. On the fourth day the taste of the mouth became still more unpleasant, along with nausea and putrescent eructations. At last two pieces of coagulated blood of considerable size were expectorated, after which the voice was restored, and all the morbid symptoms subsided.

Cæsarean Section.—Mr. Balfour, surgeon, H.E.I.C.S., was called to a dwarf, four feet high, with distorted limbs and considerable curvature of the spine, who was said to have been in labour for ten days. The bladder was found much distended, and rising above the umbilicus; the uterus inclined towards the right side; the internal parts were very much swollen and livid; the vagina discharged a fetid sanies. The head of the child was discovered resting on the brim of the pelvis, and one hand was lying in the vagina, the antero-posterior diameter about one inch and a half. An injection and opiate were given, and in the afternoon an attempt was made to relieve the bladder, but in vain, in consequence of the urethra being doubled over the brim of the pelvis. The viscus was consequently punctured in the median line a little above the pubes, and had an immense quantity of urine evacuated. The Cæsarean operation was then performed in the usual manner, without loss of blood; the bowels were carefully returned, and the wound, six inches in length, brought together with the interrupted suture and cleaned with cold water, a catheter inserted in the bladder, and an opiate given. For two days the patient seemed to be doing pretty well, but on the third pain suddenly set in on the right side, which was followed by death in a few hours. Dissection showed a soft yellow liver, and considerable peritoneal inflammation; the wound in the uterus was dark-coloured, and almost sloughy; that in the bladder was closed, and showed no symptoms of inflammation, the external wound being pretty firmly united throughout its entire length. The antero-posterior diameter of the brim was, after the removal of the bladder and rectum, under $1\frac{1}{2}$ '' of an inch. It was thought that, if the operation had been performed the first or second day after the commencement of labour, the patient might have been saved.

Imperforate Anus.—Dr. Keiller communicated to the Edinburgh Obstetric Society two interesting cases from Dr. Lyell, of Dundee. In the first the usual operation was performed, but was not followed by any permanent benefit, though done thrice during a period of six weeks, at the end of which time, some feculent matter was observed to pass with the urine by the urethra, and in a few days afterwards the feces totally ceased to be emitted by the artificial anus, which soon became obliterated. For a year the child continued well, passing its feces by the urethra, when a complete stoppage occurred of both feces and urine from obstruction of the passage, and death supervened. Dissection showed that at each operation the cut had been made into the urinary bladder, into which a small and imperfect gut was found to terminate, there being no regular rectum sigmoid flexure or descending colon present. The obstruction was found to have taken place in the prostatic portion of the urethra, which was completely filled with a substance resembling skins of raisins, coated over with brown calcareous deposit. It is remarkable that for the first six weeks the urine was passed without any admixture of feculent matter, and that this latter should escape without any admixture of urine through the artificial opening.—In the second case, the child lived twelve weeks, evacuating the feces by the mouth. No operation was attempted, and the anatomical peculiarity was found to consist in the colon terminating in a large globular *cui de eas*, which floated loosely among the other intestines in the umbilical region.

Fibrous Tumours in the Unimpregnated Uterus.—Dr. Simpson called attention to the manner in which nature sometimes proceeds to stop the progress of these tumours, by gradually transforming them, first, into a cartilaginous, and then into an earthy and almost inorganic mass, not

prone to enlarge or change its condition. This seemed to indicate the death, or at least the cessation of the reproductive action, of those cells which form the essential growing constituent of the tumour. The interesting experiments of Rayer were quoted, in which that pathologist induced the artificial transformation of normal fibrous tissue into cartilaginous and osseous substance by repeated irritation of it. Dr. Simpson thought from these circumstances* that the repeated transmission of a galvanic current through the tumour might possibly produce the required degree of irritation and its desired result.

Malignant Osteo-sarcoma at the Base of the Skull.—Dr. R. W. Smith presented to the Dublin Pathological Society a section of a skull, as a specimen of a disease of the bone. An old man, who made no complaint except of uneasiness in the head, deafness in the left ear, and an inability to respire freely through the nares, was admitted into the hospital of the South Dublin Union. After two months, without any variation in his symptoms, he died suddenly of hemorrhage from the mouth and nares. In the stomach was found, at the post-mortem examination, a quantity of blood which had been swallowed. At the base of the skull was a malignant osteo-sarcomatous formation, within which was a cavity still enclosing a clot. This malignant structure was a new growth, which had filled the sphenoid sinus and the superior cavities of the nares, and obstructed the Eustachian tube of the left side. The basilar process of the occipital bone was destroyed, as well as the body of the sphenoid, the lower portion of which remained in a softened state: part of the ethmoid bone was also destroyed. The roof of the mouth was softened, but its form was preserved, as frequently happens when the bony palate becomes affected by malignant disease.

Fulminating Mannite.—M. Sobrero has converted the peculiar kind of sugar obtained from manna into a highly fulminating compound. The process is not known, though there is little doubt that the conversion is effected by the agency of sulphuric and nitric acids. It has been employed as a substitute for fulminating mercury in percussion-caps. He found that a small quantity of mannite crystallized from alcohol, and thus employed, discharged a gun as effectually as if fulminating mercury had been used.

REVIEWS.

Cholera, Dysentery, and Fever Pathologically and Practically Considered; on the Nature, Causes, Connection, and Treatment of these Diseases, in all their Forms. By CHARLES SEARLE, M.D., M.R.C.S.E., &c. London: John Churchill, 1847; pp. 128.

Cholera is a disease which has attracted greatly the attention of the medical profession within the last few years, as numerous works which have issued from the press abundantly testify. A great amount of talent has been brought to bear upon the subject, and no labour has been spared in order that some light may be shed upon the pathology and treatment of a disease confessedly the *opprobrium medicorum*. It is an encouraging fact, that, while men of high standing have differed greatly from each other in some most important points, much valuable knowledge has been attained; and the experience of the first thirty years from the apparent commencement of this disease will materially assist future investigators in attaining such an amount of information as shall bring more under the control of medical skill this frightful malady.

Dr. Searle is a gentleman who has had ample opportunities of studying this "scourge of India," having been a medical officer in the Honourable Company's Service for many years, during which time he not only had the care of

a very large number of patients afflicted with this disease, but was himself the subject of it. He is a veteran author on the subject, and has been induced to take pen in hand in consequence of the disease having prevailed with unusual fatality in our Eastern empire during the past year; and because the disease is also extending in the direction it took on the occasion of its visiting Europe as an epidemic in 1830—the profession being as much baffled as ever in its treatment.

As the work is intended for circulation in the Indies as well as in our own country, it is addressed to the public as well as the profession—numbers of persons, both civil and military, in the East, being very frequently out of the reach of medical assistance, and to whom, therefore, some knowledge of the disease must prove of value in the hour of need. There is something about the preface which we rather like, as it contains none of that namby-pamby trash so disgusting to intelligent readers. Some may be inclined to think the author a little egotistical in what he there says; we, however, are disposed to consider the tone of independence which is assumed as the product of a mind conscious of its own advantages, but ready to impart to others that valuable information it possesses.

The work is divided into four chapters and a supplement, in which we have the disease presented to us in all its bearings. First, as regards its nature; then its most frequent causes, and the operation of those causes in developing the symptoms; next, the indications of cure, as pointed out by nature; and, after this, the remedies which principle directs and experience has proved to be most successful in its treatment. This is followed by a detailed account of the practice which should be pursued, from the first moment of visitation and through the various stages of the disease, in all its forms, from simple diarrhoea to its severest species, including that, also, of dysentery; and, subsequently, the treatment of the inflammatory febrile affection, which so frequently succeeds to the attack of cholera, is also particularized. This is followed by the subject of fever, the phenomena it exhibits, and the methods of cure which should be adopted.

After stating the causes and symptoms of the disease, we come to the indications of treatment.

Taking nature for our guide," observes our author, "the indications of treatment are obviously to excite the secretive function of the liver, and to remove the congestive accumulation of blood from the vessels of the stomach and bowels. These are the chief indications, and speak at the same time to every man's common sense as to their propriety. Another indication presents itself to our notice, which is to supersede or neutralize the poisonous agent, or cause, with which the vital stream has been contaminated, by the introduction into the blood of some other agent of an opposite description or antagonist character. These are clearly the indications of treatment, and the whole of them, under ordinary circumstances. But under extraordinary circumstances, as in the epidemic visitation at Kurrachee, or in severe cases, I should add, and strongly advise, augmenting the amount of vital air in the system, by the inhalation of oxygen or the nitrous-oxide gas: inasmuch as the epidemic cause, in the instance alluded to, must directly and immediately have diminished the amount of oxygen inhaled, and arrested, also, the exhalation of carbonic acid gas; and in thus operating must have virtually poisoned the blood, and for which, in either case, oxygen would prove a direct remedy. Independent, however, of the above views, there are others which still more strongly point out to us the necessity and importance of this remedy in all severe cases of this disease: for whether the cause operate from without the system—in diminishing the supply of oxygen or the exhalation of carbonic acid, or from within it—in diminishing the power of the organs concerned in the absorption or reception into the system of the one, or the expulsion of the other, the effect is actually the same in both cases;

and as the disease progresses, the coldness and inertia of the system point out to us but too clearly that this, the respiratory function, the primary one of life, however affected, is seriously impaired; this remedy—the introduction of oxygen into the system—cannot, therefore, be too strongly and earnestly recommended to adoption, and it is as much the duty of the medical attendant to prescribe as any of ordinary and more frequent application. Of the ghastly and livid hue which characterizes the countenance, like that of a person suffocated, and often prevades the whole body of those affected at an advanced stage of the disease, the above view offers at once an explanation."

Much has been said and written about the inhalation of gases in the treatment of severe diseases, and yet, up to the present time, they are very little employed. This arises in a great measure, no doubt, from the trouble which is necessary to procure them. Oxygen and nitrous oxide cannot be kept in the dispensary like a drug or chemical, but must be made as they are wanted. The former may with comparative ease be produced, in the way the doctor mentions at the end of the book, by the admixture of chlorate of potash with an equal proportion of powdered black oxide of manganese, and applying the heat of a spirit lamp; but the nitrous oxide is not procured so readily in a fit state to be taken into the lungs, in the way mentioned, when the process is to be conducted by a person who has had but little experience in the matter. We have seen some very awkward and very unsuccessful attempts at gas-making by some very good surgeons, and who have, in consequence, been very little disposed to employ them frequently as agents in the cure of disease. Calomel, bleeding, saline clysters, emetics, nutritive and other injections, are remedies which are advocated by our author according to the circumstances of the case. He also recommends as a very efficient agent, and one always at hand, common salt:—"Its operation is twofold—that of a stimulant and evacuant; and is much, therefore, to be preferred to brandy, and this class of remedies, which have been too commonly employed. Half an ounce of salt, dissolved in half a pint of warm water, should be immediately swallowed, and the same dose repeated every ten minutes, till it operates effectually as an emetic. After which, the same quantity of salt, being dissolved in as much cold water, should be given in doses of two table-spoonfuls every half hour or so, assisting its operation on the bowels by a clyster every hour of half a pint of the same solution, of milk-warm temperature, and repeating both till feverish heat and excitement become developed, or cold water is urgently desired by the patient, when they may be continued at longer intervals, and a wineglass full of cold water given occasionally between the doses of the solution."

We have in general a very great dislike to books written for the public and the profession, but the little treatise of Dr. Searle will, we have no doubt, prove useful to both. Residents in India who are unable to procure medical advice will find the information here given of great value to them, while the members of the medical profession will treat with respect the opinions of a gentleman whose experience on the subjects of which he treats has been very considerable.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any bookseller or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Algerslein Carfrae, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 15s.; Quarterly, 6s. 6d.

Mr. Edsall.—The omission shall be rectified. A Student, West End.—The abuses of which our correspondent complains should be clearly stated

and authenticated. The name, of course, will be given in confidence.

A Candidate.—We cannot spare room for the insertion of the questions; they are left at the office, as requested, and may be obtained on application.

An Army Surgeon.—We are sorry there is no redress; the command is at present not to be altered, and our correspondent should make himself an adept in the important art by practice. We know of no persons who would willingly undergo the operation. The neighbourhood of St. Katharine's Docks and Tower-hill might furnish some who would submit for the consideration of a little "grog."

Chemicus.—The "disinfecting fluid," we believe, is very efficient in removing the smell from foul drains, water-closets, and putrefying animal substances. Consult the Editor of the Pharmaceutical Times.

Independent.—The remarks on "The Putney Inquest" cannot be inserted without the name of our correspondent.

Rusticus.—The insurance could not be effected in a safe office for £1000 for much less than £80 per annum.

Beta.—Dr. Shirley Palmer's "Pentaglot Dictionary," published by Longman and Co.

M. D.—There is danger in commencing practice without the license, and while the Society might not prosecute there might be others who would.

Juvenis.—The surface of the diseased gland is generally mottled or speckled, with uneven projections; in some instances it is quite rough and scabious; the size and consistency of the organ are equally liable to vary. In the early periods of the disease it may be found larger than natural, and of softer consistence; in the advanced stages, contracted in bulk and hard. When cut into, it will be found that the outer portion of the organ is the chief seat of disorganization. It is granular, and generally of a pale yellow colour. The medullary structure is seldom much altered.

Mr. Chance.—There is no certificate required to engage in the business of a druggist. In country places very ignorant persons sell drugs and chemicals, and arsenic may be obtained with as much facility as a dose of Epsom salts.

A Subscriber.—We do not understand what examination is referred to. The Apothecaries' Company requires such a knowledge of Latin as will enable the candidate to read Celsus and Gregory grammatically. The College of Surgeons is satisfied with plain English, and if the examiners are in a good temper a very small quantity of the mother tongue will do.

Scotus.—The diploma is a proper qualification. A duly-qualified practitioner, possessing a single diploma is entitled to give evidence in courts of justice.

Accoucheur.—The question is not yet decided. There is no fixed number of days, and the most eminent practitioners have not been able to agree in their opinions.

A Practising Apothecary.—Druggists too frequently play the part of medical practitioners, and the Registration Bill would have perpetuated these privileges. The publication referred to has often urged the druggists to practise, in defiance of the Act of 1815, though it professedly advocates the rights of medical men.

Mr. Francis Cuthbert's case does not need the extended notice he requests, the subject, having of late been brought so frequently before the profession, has lost much of the interest which it originally excited.

Amicus.—Apply to Mr. Baillière for a catalogue of French works; our correspondent will then be able to choose for himself.

Alpha.—The letter has been unfortunately mislaid, and we shall, in consequence, feel obliged for another copy.

A Constant Reader had better apply to Mr. Martin himself, who will, no doubt, give him all the information he seeks.

A. W. Close, Esq., Grosvenor-street, Manchester.—We shall be happy to hear from our respected correspondent. The communication was received last week, but, by an oversight, was not acknowledged.

Censor, Hackney.—Mr. Cooper's Lectures will be proceeded with till completed; the other suggestions will be attended to.

Ambrose Pare informs us that, "The first English medical man who noticed the smallpox in Great Britain was the celebrated Thomas Sydenham, and that he was the first who wrote of it as a distinct disease (from rubeola). Rhazes, an Arabian physician, was the first author who expressly treats of smallpox; but he confounded it with measles, and the two continued to be viewed as modifications of the same disease till the time of Sydenham."

Z.—We are sorry that our correspondent was not successful in passing an examination at Somerset-house. The degree is a respectable one, and a little attention to chemistry will overcome many difficulties. The examination at St. Andrew's is, no doubt, a practical one, and will, perhaps, better suit the case of a gentleman who has been many years in practice than the other.

Dr. Wake, Southwold, Suffolk.—The editor of the Pharmaceutical Times will be able to give our correspondent the information he seeks.

M. D., Newport.—An advertisement in the Medical Times would be the best means to adopt.

J. R. K., Burslem, Potteries.—"Quain's Anatomy" is a work which will just suit our correspondent. It is of the utmost importance that the student should have fresh information in a division of his studies, when from day to day new light is being introduced, more especially from the improving application of the microscope, and other means of observation and analysis. This valuable work will furnish all useful information.

An Old Subscriber.—With a country certificate, without paying the additional £1, a debt cannot be recovered.

Several correspondents have asked us for the rules and regulations of the Medical Benevolent Institution; if the Secretary will send them to us they shall be forwarded.

If Mr. Farmer will send us a full statement of his case, authenticated with his name, it shall be published. The same also must be said in reference to the communication from A Medical Juror.

Letters and communications have been received from Mr. R. Brandon, Russell-street, Bloomsbury; A Practising Apothecary; Mr. Francis Cuthbert; Amicus; Alpha; A Constant Reader; A. W. Close, Esq., Grosvenor-street, Manchester; Censor, Hackney; Ambrose Pare; Z.; An Old Subscriber, Twickenham; Dr. Wake, Southwold, Suffolk; Mr. F. Page, Newmarket; M. D., Newport; Accoucheur; Scotus; A Subscriber; Mr. Chance; Juvenis; M. D.; Beta; Rusticus; Independent; Chemicus; An Army Surgeon; A Candidate; A Student, West-end; Mr. Edsall.

THE MEDICAL TIMES.

SATURDAY, AUGUST 28, 1847.

MEDICAL REMUNERATION.

"Multa dies variisque labor mutabilis ævi
Retulit in melius: mihi tos alterna revidens
Læst, et in solido rursus Fortuna locavit."
VIND. ÆNEID., lib. 11.

At no time in the history of the profession has there ever been exhibited by its members such a lively sense of their real condition, or have such vigorous efforts been used by them to attain their legitimate position in society. A few years back the struggles for emancipation were but few and insignificant—the spasmodic indications of life and not the robust actions of consolidated energies intelligently directed. This naturally resulted from the manner in which the profession was constituted: the "pure" physicians and surgeons possessing corporate privileges, and arrogating to themselves the learning and emoluments of the medical art; while the general practitioners were scattered throughout the length and

breadth of the land, unknown in their collective capacity to Government or people. There has never yet existed a single medical corporation that has claimed affinity to them, or has exhibited any real concern for their welfare; on the contrary, the majority of these institutions have manifested a determined opposition to sound medical reform, from which alone can spring all that is honourable and advantageous to general practitioners.

While, however, the corporations are guilty of numerous acts of oppression, medical men have to blame themselves for much of that reproach which has been heaped upon them, as well as for that low scale of remuneration they receive for their important labours. Neither Government nor poor-law guardians would have dared to offer such low sums for medical attendance upon sick paupers if the attendants had only been true to themselves. There is not a parish throughout the kingdom, that we know of, that has ever been compelled to raise the salaries of medical officers, because none could be found to undertake the duties for sums which would not purchase the drugs required by the sick, much less remunerate the practitioner for his time and skill. Only a short time ago, when the Liverpool select vestry, with the rector as chairman, advertised for medical officers, the pile of diplomas and testimonials which were sent in from a host of candidates excited the ridicule of the parish worthies, who had just before grossly insulted the gentlemen who gratuitously attended the sick poor. Halifax exhibited a bold front when requested to give a little more than 3s. 6d. for a professional visit to a pauper; and, while drawing the purse-strings tight, laughed in the face of the remonstrants. The Lords of the Treasury, with their five shillings a day for physicians and surgeons attending Irish fever hospitals, very snappishly answered it was enough, when the protest of more than a thousand medical gentlemen was sent to them.

And how has this come to pass, that the services of medical men are considered of less value than those of the mechanic? Because—and we repeat it—there has not been that unity of purpose amongst them—that professional amenity towards each other—that proper estimation of their own skill which becomes individuals belonging to an enlightened and educated community. If they will depreciate their own worth, it is not to be expected the public will do otherwise. Under the old law, when parishes were let by tender, and those who would do the most work for the least money were elected medical officers, the most insignificant sums were often asked and received, either to balk a rival or to please some influential persons in the district. The young surgeon, when he first commences practice, considers himself doubly blessed if elected parish doctor, while those upon whose domain he intrudes think it no small triumph to frustrate his ambitious hopes. The eagerness which is manifested for offices of this kind leads guardians to suppose that they have a valuable living in their gift, and they bestow it upon their favourite with all the impudence of dogs in office. There is not a village club which pays the handsome sum of two shillings and sixpence a head per annum to the doctor for visits, medicine, and attendance upon sick members, that is not courted for its favours; while advice gratis to the public at large has become so common, both in London and the provinces, that a bill for medicine, &c., will eventually be considered quite a curiosity. The charitable institutions, moreover, which

are said to be "the glory of our country," are the means of vastly depreciating the value of professional services. Many of these establishments are got up for no other purpose than that of promoting the worldly interests of a few physicians and surgeons, at the expense of a large number of general practitioners. The ostensible object of hospitals and dispensaries is to relieve the indigent sick, but numbers who are well able to pay a medical attendant are allowed to become patients—a ticket being easily procured by any one who chooses to ask for it. The extent to which this is carried on in the metropolis is, perhaps, not thoroughly known, and the injury which it inflicts upon the profession not clearly understood. Only a few years ago a hospital was founded in the western part of London, under royal patronage, which not only received patients into its wards, but the governors had such an enlarged benevolence as to sanction the visits of the medical officers to the houses of noblemen and gentlemen, who subscribed a certain sum to the funds of the institution. Fortunately for the members of the profession in the neighbourhood, the governors and medical officers waged war with each other till the hospital became a bankrupt concern, and at length ceased to exist. Every medical institution established for the relief of the sick poor, when it affords advice and medicine to those who can pay for it, is guilty of robbing the indigent, and of acting unjustly towards the profession.

We are aware that it is no easy task to expose and resist the abuses which live in these places—the welfare of the profession, however, requires it, and the members must take the lead in the great work. In defending their own interests they become the champions of the poor, who have no means of protecting themselves. Medical remuneration is low, because medical men are unjust to each other; the evil, however, may be remedied. It is only required of them to be united and persevering—to regard in a proper light the value of their own services—and they will then find a greater disposition in the public to act liberally towards them.

THE MODESTY AND MAGNANIMITY OF THE APOTHECARIES' SOCIETY.

"Opifexque per orbem dicitur."—OVID, MET.

The Apothecaries' Company, which two years ago was lauded by the profession for its efforts in favour of a liberal medical education and of substantial reform, has within the last few months become rather unpopular, from the apathy which it has manifested in prosecuting unlicensed practitioners. There is no doubt that these have greatly increased since the Medical Registration Bill was last introduced into the House of Commons, and they have more daringly exercised their iniquitous vocation because of the unsettled state of medical politics. Scarcely is there a town or village in the kingdom in which some charlatan is not found who exercises his profession at the expense of legitimate practitioners in medicine. We know of instances where some country surgeons have been permanently injured, and others entirely ruined, by the impudent artifices of designing quacks, who, devoid of principle, prey upon the public health in order that they may abundantly furnish their own pockets with gold.

We are aware that, in many instances, there are difficulties to be overcome which appear almost insurmountable, in order that these offenders may be effectually punished; yet obstacles

ought not to deter those who are invested with authority from using it in such a manner as to afford all possible protection to medical men and the public.

It is established beyond doubt that an indictment would lie against any person who had practised as an apothecary without a legal qualification, and it is equally certain that this might be preferred at the instance of a private prosecutor. But if the law were left to be worked out by the efforts of individuals, there is no doubt that it would speedily become a dead letter, as few would like to subject themselves to the odium which proceedings of this kind would entail upon them, or to the loss of time, if not of money, which they must necessarily suffer. The Company ought, therefore, under present circumstances, to undertake the work when there is a fair prospect of success; and in every doubtful case, the officers should explicitly state their reasons for declining to prosecute. Many cases, it is probable, are brought before them with which they could not interfere, and it seems there are others which fall to the ground for the want of funds to prosecute. We really pity the Society, because, after it has been engaged for so many years in the business of drug-selling, and with a considerable revenue from the sale of its certificates, its coffers are now so low as not to permit it doing all it could in the way of punishing quacks. This cry of poverty comes with rather an ill grace just now, especially as there is an impression abroad that the Company is anything but poor. Surely the money which is received in the course of the year from those who are admitted licentiates is amply sufficient to protect them afterwards from illegal practice; if not, an appeal to the profession would be resorted to in such a manner as would remove every difficulty in the working of the law for the want of funds.

In the notice recently issued from the Hall, we find it stated that "It is essential, also, that the inability of the Society of Apothecaries to institute prosecutions in every case of illegal practice in which their interference is called for, should be distinctly made known, in order that other parties may not be deterred from putting the law in force, under the impression that the Society of Apothecaries are able to take that duty upon themselves."

This is certainly a very odd paragraph, and one which we can scarcely understand. Does the Society mean to say that while it would be ashamed to institute proceedings against certain practitioners, not quacks, but who do not possess the certificate, it would be very glad to see others do the work, and that there is no necessity for the exhibition of modesty on the part of private individuals, though it is very proper on that of the Society? This is capital, certainly, and we hope speedily to be informed why, if a prosecution can be sustained, the Company in every instance should not undertake it.

In the paragraph which follows, there is a show of liberality, where it is written, "But although the Society cannot institute legal proceedings themselves in every case to which their attention is drawn, they are able, and will be found ready and willing, to afford to all parties who may be desirous of preferring an indictment against a person practising illegally, such advice as the Society's experience in the administration of the Apothecaries' Act may enable them to give; and their law-officer has received instructions, upon application from such parties, to render any as-

sistance and information in his power as to the mode of proceeding against illegal practitioners, and as to the nature of the evidence by which a prosecution must be supported."

Now, this is very kind of the Society, to put forward their licentiates as puppets, while it stands behind pulling the strings and directing their movements. It is a sort of magnanimity which will be duly appreciated by the profession, and the "advice gratis" will confer upon the corporation of Water-lane a new kind of popularity which even the worthies of Lincoln's-inn-fields will not be disposed to seek after.

The licentiates having been informed of the high privilege which they possess, of taking the law in their own hands, are urged to do so without delay:—"The Society of Apothecaries, therefore, under a conviction that increased security to the public health will result from an efficient execution of the law which forbids the practice of medicine by those who have not given evidence of their possessing adequate skill, beg to urge upon the public authorities, upon medical associations, and upon individuals, the importance of putting the law in force against offenders in such fitting cases as may come under their immediate notice. The Society themselves have, in the meanwhile, instituted several additional prosecutions against illegal practitioners, which are now in progress."

Does the Company really imagine that their licentiates will be such noodles as to act upon the suggestions here made? We do not think so, for we are firmly persuaded they have too much regard for their own characters, to become informers against parties whom the Company would be ashamed to prosecute.

Every day brings to light facts which prove the necessity of granting a charter of incorporation to general practitioners, where they can elect their own officers, and enjoy such privileges as shall protect them from competition with illiterate quacks, without the necessity of undertaking personally the office of public prosecutor.

THE NAVY AND ITS APPOINTMENTS.

Every day offers cases of public importance to illustrate the influence which the medical profession has secured with Government after thirty years' agitation.

Our readers remember the celebrated expedition to the North Pole, under Sir Charles Clark Ross. Two surgeons and as many assistant-surgeons accompanied that eminent commander in his perilous voyage; and it was, of course, mainly to their scientific skill that the remarkable preservation of the large party (not one life being lost) was owing. Well. The whole of the executive, from the commander down to the humblest clerk, have received rewards and promotions (several very satisfactory). But not the medical staff. They hold precisely the same grades now as on setting out in the expedition seven or eight years since!

We need not say that in the navy there are several surgeons of long standing and of the highest claims to promotion by their connection with similar perilous scientific enterprises. A short time since there was vacant the appointment of deputy-inspector; and to this turned of course the ambition of many gentlemen in the position we have described. The gentleman who has secured it, though, no doubt, a very worthy and honourable officer (Mr. Drummond), had no claim (save *equal standing*) that we know of, except that for some time he had held the appoint-

ment of private surgeon to Lord Auckland. As if to show further that luck is better than merit. Mr. Drummond has comfortable home quarters in the Marine Hospital, Woolwich.

This usual, but not, therefore, satisfactory, instance of patronage has just been followed by another. If we are to believe the *Morning Herald* of the other day, Mr. James Wingate Johnston, a gentleman who has had the advantage of winning his services in the lucrative arena of convict transports, has just received another deputy-inspectorship of hospitals. To say nothing of others, as of McWilliams, Robertson, &c., Mr. Johnston is five years the junior of the gentleman who had the chief medical superintendence of the Arctic expedition under Ross!

We shall conclude with one more fact. In connection with naval services performed on the African coast, every officer engaged in the dangerous mission has been promoted, with the exception of the medical officers.

THE ROYAL FREE HOSPITAL.

THE death of Benn, and the inquest, recorded in another page, illustrate with what ease in this country of abundant workhouses and superabundant hospitals, the victims of destitution can be hurried into the next world. It is a striking argument of the efficiency both of voluntary and statutory charity. A poor wretch, suffering alike from disease and inanition without a friend or an adviser, naturally singles out from all our charitable institutions the one that has been most trumpet-tongued in its professions of unlimited and unrestricted benevolence; and, crawling to the much-desired asylum, the advertised sanctuary of the wretched, supposes himself at last havened where exhausted nature may be recovered, and the mischiefs of a wrecked constitution repaired. He comes not only well, but well-timed; and he is at once ushered into the presence of the Founder and principal Surgeon of the charity. If ever there was a test of the professions of the Royal Free Hospital it was assuredly here. While a shilling was in its coffers there could be no more fitting recipient: the whole trusteeship of the institution was void, if there were no advantage in it for this poor wretch. But what happened?

Benn is examined by the surgeon; it is not pretended or insinuated that there was any mistake in the diagnosis; the Surgeon and Founder *knew* that, if his institution did not immediately succour him, twenty-four hours was the outside tenure of the poor man's existence. Yet there was no admission!—and the wretch who had crawled so far for what he thought sure help, has now to crawl further for that on which he can place only secondary reliance. He scarcely leaves the inhospitable door of that free institution, which had so raised and belied his hopes, before nature fails him, and he sinks to the earth all but dead—his only protest against the deplorable and murderous deception which has victimized him.

Why this refusal, this repulse? This is a question which demands not only an explanation, but one full and satisfactory. We have here involved, indeed, a matter of primary importance to the public as well as to the benefactors of the hospital. The existence of such an institution is a public fact, and if, instead of being a free hospital, it be, as in this case, a free and perilous one, public humanity as well as justice requires its extinction.

Had there been no Royal Free Hospital it is extremely probable that this poor man would have

found with less exertion and pain, a nearer asylum, where his life might have been, if not saved, at all events much protracted. We have looked through the details of the inquest in vain for any answer approaching to full or satisfactory. If the death lie at the door of the Royal Free Hospital, its managers have in no way relieved themselves from the responsibility. But before we investigate the sort of answer that has been given, let us not refrain from condemning in the strongest manner the magisterial course which denied a fuller exposition of the facts of the case. There were no nurses summoned from the hospital, nor any effort made to have their attendance enforced, yet they could have given important evidence as to what beds were full, and as to what were the means of the hospital to receive the patient. When questions were put to the porter, with a view to elicit information on these matters, the interrogators were silenced, and the questions not allowed to be put by the magistrate. The only party permitted to give any information on this subject was Dr. Marsden, who cannot tell us whether the number of patients actually in the hospital was thirty or forty, but speaks of them with the utmost vagueness. We have, therefore, no means of knowing to what extent the hospital is answerable for the death of Benn. What little evidence we have is from the party principally inculpated, and this evidence is vague and indefinite, and if it lead to any presumption it is to one against him. We must, indeed, form our conclusions rather from reasoning than from evidence, and where we have not sufficient information wait till we obtain a clearer light.

Dr. Marsden tells us that there are beds for 140 patients in the hospital, and says that there are two wards containing each fifty beds closed. Are there then forty beds in actual service? If so, and there were only from thirty to forty patients within the walls on the day of Benn's application, how happens it that that poor man was denied admission? The porter speaks of having power to receive accident cases; if so, how, again, happened it that Benn was refused because there was no vacant bed? Dr. Marsden swears that there was no bed unoccupied; how then could there have been instructions given to the porter to admit accidents? How, again, happens it that with forty beds there were only from thirty to forty patients? These are very important inquiries, and, if it be now late to put them, the more must be our regret that during the inquest information had not been sought on them by him on whom the law imposes the obligation, and to whom it intrusts the power.

We now, therefore, ask for what the coroner should have asked: a plain downright authenticated statement of the names of the—between thirty and forty—patients who, on Friday, August 6, tenanted the forty beds which, out of 140, were open to charitable use. There must be no concealment on this matter: it is the duty of the parties connected with the hospital to see that his suspicious, because inexplicable, circumstance should be investigated and properly submitted to the public.

The coroner must deeply regret that he allowed his deplorable obscurity to rest over the conduct of the hospital administration. No one should have felt more strongly than he the necessity of fully examining every person connected with the hospital, who could have given a scintilla of evidence on this deplorable transaction. He must feel that instead of preventing Dr. Worthington and the "Guardian" from inquiring into these mat-

ters, he should have lent them all the aid in his power for achieving the elucidations they sought. The public know that, while the institution is receiving from five to nine and ten thousand pounds per annum, he, that very coroner, is one of the managing committee that disposes of those funds; that his son, in consequence of negotiations with Dr. Marsden, the inculpated founder of that institution—the coroner's son—is one of the three surgeons to the hospital; that the coroner's own personal management of the institution and its funds was under trial at that inquest in connection with the death of a human creature; and, therefore, if on all coroners the necessity of a full and satisfactory investigation be imperative, it was much more so on him from the extraordinary position in which an ill fortune had placed him.

But what makes all these considerations far more pressing and overwhelming is the fact that this very coroner, a manager of the institution, and father of one of its surgeons, had, in his capacity of editor of a weekly journal, and previous to the adjustment of his personal differences with Dr. Marsden and to the appointment of his son, published insinuations and accusations directed against the character and government of the institution of the gravest hue. Professing to answer correspondents, he thus wrote of Dr. Marsden and his "charity":—

"Senex, a Lover of well-audited Accounts.—"The constitution and government of the hospital (Royal Free) are, we acknowledge, proper subjects for consideration and discussion. Ten thousand pounds of public money were thrown into the coffers of the Royal Free Hospital in 'the last year.'—*Lancet*, Nov. 9, 1844.

Subsequently he published the following mysterious threat:—

"Several further communications respecting the appropriation of two beds in the Royal Free Hospital, &c. * * * Some of the letters refer rather to private than public transactions, &c." * * *.—*Lancet*, Nov. 16, 1844.

And a little later he thus more clearly shadowed out his accusations:—

"Observer' is desirous of learning what is the amount of salary or per centage received by two well-dressed persons whose business it is to beg for subscriptions for the Free Hospital in Gray's-inn-road? He adds 'that surely one such person would be quite sufficient to draw upon the funds of the hospital.' For ourselves, we may state that we cannot give a definite reply to the question. A general meeting is held annually in February, and it is likely that at the next meeting many interrogatories of the description here proposed will be submitted to the committee, and that the finances of the institution will be subjected to a thorough investigation. Nothing, in our opinion, is more detestable than to see any institution trumpeted forth as a 'public charity,' if it be used for private purposes by individuals who boast of their philanthropic services. Several establishments of this description have lately been brought under our notice, and, we believe, that two of them will be found to contain the most curious accounts which have ever been published, relative to the frauds which are committed in the metropolis under the much abused name of 'charity.'"

If such was the character of the management of this hospital before the coroner was elected to the committee, or his son appointed surgeon, what has happened to assure us of a change subsequent to those two events? Did the coroner

charge his present associates with what they were not guilty of? If he did, where is his public apology and retraction? If he did not, are his associates reformed, converted, regenerated? What is the *real* practice, what the real character of the hospital management? If this thing demanded an investigation when, with 140 beds open, a poor girl was denied admission, is it demanded less now when, with an income of many thousands, and with only from between thirty-six to forty inmates, it still turns out a poor man to die at its very portals? Certainly, there is something here on which we should have a far fuller investigation than was afforded us on the day of the inquest. *And we shall have it.*

NOTE FROM MR. PENNINGTON.

SIR,—Will you do me the favour to insert this note in your *Medical Times*?

From unavoidable circumstances I was prevented attending the meeting of the National Institute.

The editor of the *Lancet* has drawn an inference that I have deserted the cause.

It has now, and ever will have, my warmest interest; respecting the event, I never was more sanguine.—I am, Sir, yours, &c.,

R. R. PENNINGTON.

Portman-square, Aug. 25.

LITERARY AND PARLIAMENTARY QUACKERY.

(LETTER FROM DR. EDYE AND SON.)

(Continued from p. 516.)

SIR,—I said that the "Müller" trick was clever, dashing, unique. The conjuror, if he did not exactly get *into* the quart pot, as he promised, got out of it as he could hardly have expected. The favour he conferred on his readers by the pledge of upwards of "twelve hundred highly finished engravings," and an expenditure of "many thousand pounds," was only equalled, as he logically showed, by the favour he did them in *withdrawing* from the benefaction. After playing with his subscribers' vanity for months by bubble promises of the most brilliant texture, he then, and with as much success as the polite Frenchman, gives a hearty kick to a certain locality of his subscribers' persons in so adroit a fashion that it was felt to be a delicate mode of administering a further compliment! But then, if he did not give "Müller and the thousands of pounds," he would give something else. Elliston, for one of his benefits, roused provincial curiosity and excitement to their *acmé*, by a similarly impossible pledge of a "brilliant display of fireworks from the stage of the theatre," the original cost of which was also "many thousand pounds." The theatre was crammed to suffocation—expectation at its highest pitch—enter Mr. Elliston. "Rejoiced at so crowded an auditory"—"had prepared a magnificent collection of pyrotechnics"—"unfortunately at the last moment the proprietor had put in his veto"—"unfortunate—very—but—but—to compensate them—the orchestra [three shabby-looking fiddlers] would play them 'God save the King'!"—"Gentlemen, strike up!" *Est!* Mr. Elliston with a very pompous strut. Müller is our friend's "pyrotechnics"—and for 'God save the King' we have the great compensation—*Matteucci!* Wakley cannot give the course, costing thousands of pounds; but he can—*say*, and *will*—give them in worse English, a bad French translation of a very ordinary Italian monograph!

Our friend's scientific translations are always odd illustrations of a species of quackery to which he claims an exclusive title. At one time he had a lust for presenting every prescription to the non-learned—his readers—he seems to know them—in the humble vernacular; and hence on one occasion we had *pulvis Jacobi* rendered "powder of Jacob." *Matteucci* is given with an accuracy as harmonious. It must be a work of great authority in medical science. Without troubling you with one word of admiring comment, I will give you a *few*, a very few specimens of translating accuracy, and leave the subject till some new illustrations demand from me and my esteemed son a new encomium.

MODERN SCIENTIFIC TRANSLATIONS.

Voici un tendon, une membrane, qui tels que je vous les montre, durcis et raccornis, paraissent n'avoir jamais fait partie d'un corps organisé; cependant, si nous les plongeons dans l'eau, vous les voyez, à mesure qu'ils s'en imbibent, redevenir mous, souples, élastiques, et prêts à remplir dans le corps vivant les fonctions qui leur sont réservées.

The reader may suppose that such tendons and membranes may be *really* employed again in the living organism: *Matteucci* means that, by soaking in water, they will recover the *physical* properties which enabled them *originally* to perform the functions assigned to them in the living body—"à mesure qu'ils s'en imbibent" means *in proportion as they get soaked*, and not "according to its imbibing power." "Un liquide écumeux acide," and "un liquide alcalin," are respectively translated "a frothy liquid acid," and "a liquid alkali," instead of "a frothy acid liquid," and "an alkaline liquid."

Que ne pourrait on dire de l'ouïe et de la voix, qui sont simplement des effets de vibrations particulières de l'air, propagées par des solides, d'après les lois générales de l'acoustique?

L'action chimique de la lumière qui décompose l'acide carbonique, porte le carbone sous forme de combinaisons nouvelles dans le sein des végétaux, en dégage l'oxygène et produit ainsi ce qui les affinités chimiques les plus puissantes ne peuvent réaliser, &c. &c.

Elles sont de même nature que celles qu'exerce le noir de plume sur le mélange d'hydrogène et d'oxygène, l'argent divisé sur l'eau oxygénée.

Mais aujourd'hui nous pouvons, à l'aide

Look at a tendon, a membrane, which, as I show you, is hard and horny, appearing never to have formed a part of an organized body; yet, if we plunge it into water, you will perceive that, *according to its imbibing power*, it will become moist, supple, elastic, and enabled to perform in the living body the functions which belong to it.—(Page 579.)

Why can we not say that hearing and voice are simply the effects of particular vibrations of the air, propagated through solids, according to the general laws of acoustics? (!).

The chemical action of light, which decomposes carbonic acid, carries the carbon under the form of new combination into the interior of vegetables, disengages the oxygen, and produces such combinations as the most powerful chemical affinities are unable to effect, &c. &c.

They are of the same nature as those which the black platinum powder exerts upon a mixture of hydrogen and oxygen, and silver scattered on oxygenated water.

We can now explain, by the aid alone of the

du seul phénomène de l'endosmose, fait entièrement du domaine des forces physiques, expliquer, &c. &c.

Par ce changement de mot, on se fait une dangereuse illusion.

Voici un tube de verre; son extrémité inférieure, fermée par un morceau de vessie élargie en forme d'entonnoir.

L'acide sulfhydrique is converted by our friend into sulphuric acid.

Si l'extrémité inférieure du tube a une largeur telle que la membrane ait 40 millimètres de diamètre; et que le tube ait 2 millimètres, &c. &c.

Elles finissent par y être comprises et presque confondues lorsque ce liquide est devenu plus ou moins dense.

Even the typographical errors of the French edition are carefully copied by the *Lancet*.

Thus, at page 638, we find certain tables, in which the first and third columns are intended to indicate the volumes of liquid in tenths of a cubic centimètre; both columns are, however, marked as if they represented *grammes*; the French edition gives the weight in the second column in one instance as 47.130 grammes instead of 17.130 grammes, evidently from an error and oversight in printing, which could not well have escaped the eye of a careful translator; but the *Lancet* faithfully gives the 47.130. In the same way we find all the miscalculations of the French editor faithfully copied: 1.05 grammes is there calculated equal to 20 grains (one gramme is between 15 and 16 grains, about 15½); 0.40 gr. is considered equal to eight grains; 0.45 gr. equal to nine grains.

Dutrochet a laissé une plante exposée à l'air jusqu'à ce qu'elle eût perdu par l'évaporation 0.15 de son poids.

Le Professeur Piria a toujours trouvé du manganèse dans les graines du *lupinus albus*.

Capital fun this, Sir, in the shape of learned translation in a *learned* work? How happy is *Matteucci*! What a knowledge of French, of physics, of chemistry in the translator! How blest the readers! But I have done. I am wearied with admiration, worn out with wonder. Till the great man try his hand at a second edition of the "Secret Friend," or some work of equal celebrity, he can never after the great deeds I have commemorated do anything requiring the humble testimony of—

Your obedient servants,

JEROME EDEY AND SON

MORE WORK FOR NO PAY.

[To the Editor of the Medical Times.]

SIR,—The laurels so long and so unjustly withheld from the unhappy profession of which chance to be a member are now about to be

phenomenon of endosmose (occasioned entirely by the dominion of the physical forces), &c. &c.

By this change of the word, we become conscious of a dangerous illusion.

Here is a glass tube, having its inferior extremity closed by a piece of bladder extended in a rounded form (!!).

If a tube of 2 millimètres be closed at its lower extremity by a membrane 40 millimètres in diameter, &c. &c.

They end by becoming compressed and nearly blended together, on the fluid becoming more or less dense.

Even the typographical errors of the French edition are carefully copied by the *Lancet*.

Thus, at page 638, we find certain tables, in which the first and third columns are intended to indicate the volumes of liquid in tenths of a cubic centimètre; both columns are, however, marked as if they represented *grammes*; the French edition gives the weight in the second column in one instance as 47.130 grammes instead of 17.130 grammes, evidently from an error and oversight in printing, which could not well have escaped the eye of a careful translator; but the *Lancet* faithfully gives the 47.130. In the same way we find all the miscalculations of the French editor faithfully copied: 1.05 grammes is there calculated equal to 20 grains (one gramme is between 15 and 16 grains, about 15½); 0.40 gr. is considered equal to eight grains; 0.45 gr. equal to nine grains.

Dutrochet left a plant exposed to air until it lost by evaporation about one-fifteenth of its weight.

Professor Piria always found grains of manganese in the *lupinus albus* (!!).

Capital fun this, Sir, in the shape of learned translation in a *learned* work? How happy is *Matteucci*! What a knowledge of French, of physics, of chemistry in the translator! How blest the readers! But I have done. I am wearied with admiration, worn out with wonder. Till the great man try his hand at a second edition of the "Secret Friend," or some work of equal celebrity, he can never after the great deeds I have commemorated do anything requiring the humble testimony of—

Your obedient servants,

JEROME EDEY AND SON

called in a profusion as flattering as it is unexpected. After years of wearying and ill-requited toil in the faithless service of Apollo, Æsculapius, Hygieia, and, I might add, Lucina, we are suddenly called upon to enlist under the banners and rally round the standard of the goddess Cloacina, "chacun à son goût." By a recent act of Parliament, every practitioner of medicine, provided always he be legally qualified, shall be entitled to secure to himself the distinguished position of *honorary inspector of nuisances* in his peculiar district; and when such nuisances shall be found prejudicial to public health it shall be competent to magistrates in petty sessions to order the abatement of the same, on the joint certificate of two of the distinguished honoraries thus created. Permit me here, Sir, to congratulate you as a medical man on your newly-acquired privilege—that of dipping your nose into your neighbour's cesspool, and "all for the honour of the thing." Carefully have I perused the act in question, but not one word can I find about the remuneration to be awarded for such service; faith no! as usual, it is all to be done "pour l'amour de Dieu."

Not to waste your time and space with unanswerable argument and irrefragable proof of my assertion, I at once flatly affirm that, in any enterprise having for its true object the public weal, the medical profession of this country will ever be found to co-operate with a zeal and cordiality totally irrespective of personal interest; but that any moral obligation exists compelling them to discharge this loathsome duty *gratuitously*, I deny. What would a fair remuneration out of the public purse be in comparison to the advantages which the public would reap a thousand-fold? The duty is not an enviable one, neither is it a mere matter of form: it entails a certain amount of exposure to private pique and interested malice from those who shall be thus brought under control of the law, and no honest man will certify to that which he has not by *personal observation* ascertained to be correct. In a pecuniary point of view the medical profession have an interest in the continuance of such nuisances as are contemplated; but which of its members ever held up a hand in favour of their preservation? A principal feature in the new and summary process of abating them is a vast saving of expense to the public. Is not this itself a boon? Why, then, demand the unrequited aid of a medical man into the bargain? That, to say the least, is avaricious. Such aid, though available, is not absolutely necessary, because I will venture to assert that any man who suffers from a nuisance will, if he consult a respectable solicitor, be sure to find that "for every wrong there is a remedy;" it might be an expensive one and slow in its effect.

There is more in this new act than meets the eye: where it will be plied once for the protection of public health, it will be plied twenty times in protecting and enhancing the value of private property. The usual functionaries to whose custody the safety of man's worldly possessions is confided—to wit, policemen, constables, beadles, &c. &c.—get their regular pay; but now, forsooth, the medical man is to mount guard over these *gratuitously*. If health is the sole object, what, let me ask, is more precious? It is beyond all price, and it is not to be had, preserved, protected, and kept in perfect repair for nothing. Liberal as are the draughts upon our time and talents in behalf of the public, if we, Sir, approach Parliament in the hope of getting our grievances redressed, we are thrust out of court without much ceremony: our wrongs are beyond the reach of remedy—in fact we are slaves to whom the blessings of emancipation have not yet been extended. Amongst the many unpaid services demanded of us I might mention attendance under the Poor-law Act for (strictly speaking) no remuneration; attendance upon hospitals, infirmaries, and dispensaries; then come insurance-offices, who always want something for nothing; then clubs, benefit and friendly societies: these, too, must not only have their members attended for a shadow, but their funds protected

from invasion by certificates in favour of sick claimants.

The next and crowning novelty I presume will be an act to amend the Vagrant Act, with a clause compelling medical men to overhaul all trampers (a wise provision in these days of fever) and place them under quarantine, or furnish a clean bill of health—also for nothing.

My object in offering these remarks is to introduce to the notice of the profession the simple question, Whether they mean to submit to this new imposition? If they do, I do not; and the right hand which pens this shall never attach my signature to a nuisance-certificate till its "colleague on the left" has received a fair equivalent. I have not alluded to the gratuitous certificates of the "cause of death" which we supply, because, with few exceptions, we have granted them willingly and cheerfully, as being for a good purpose; but I must say I fear our alacrity in this has opened a door for further encroachment. To prove that he who stirs in a nuisance will get into bad odour, I might mention an instance where I refused the document required, but provided the applicant with a *local* act of Parliament which made it competent to himself to do the needful, he having "a cure of souls." From that day to this no steps have been taken, and the evil still exists—why? because a loss of popularity would have endangered a piece of preferment then pending, "if he had taken an active part." I could also tell a tale of a benefit society mulcted in the amount of £32 by trying to cheat a doctor of his fee; and an anecdote or two about insurance-offices might be added, illustrative of the maxim "that experience must be bought." I am an advocate for "Government education," and I would teach them, in the first place, *what is due to the medical profession*. As for the public, I would permit them awhile to pursue their present philosophical investigations till dear-bought experience convinces them that saving units by sacrificing tens is a financial fallacy, as exacting or expecting unpaid services from overwrought brains is a moral fallacy subversive of the creed that "the labourer is worthy of his hire." Hereafter I hope to adduce instances of the penny-wise-pound-foolish policy of such a system, and to observe on some other matters which beset with thorns our path. For the present, to such of the profession as mean to flounder gratis in public nuisances, I have only to say, gentlemen, "The more you stir the more you'll stink."

I am, Sir, your obedient servant,
QUID PRO QUO.

APOTHECARIES AND PHYSICIANS.

[To the Editor of the Medical Times.]
SIR,—O. L. T., at page 460, asks "Is not every one who practises physic without a license from the College of Physicians infringing their charter? and what clause in the Apothecaries' Act entitles an apothecary to practise physic?" Your correspondent seems not to know that the apothecaries were a recognised body, and incorporated into one company with the old and opulent *fraternity of the grocers* by King Edward the Third, in the year 1345; and that Edward's charter of incorporation was renewed and confirmed in 1429 by King Henry the Sixth, who, in 1447, granted to the joint company new powers and privileges, among which was that "of supervising, garbelling, searching, examining, and proving all sorts of merchandises, spices, and drugs in any wise belonging to medicines;" and that the corporation was required to appoint "sufficient officers skilled in the premises of this kind, to search, examine, and prove all the spices, drugs, and merchandises above specified and mentioned, whatsoever belongs to medicines, in whosoever hands they can find them."

No doubt seems to have been entertained of the right of the apothecary to visit and prescribe for persons in their sicknesses till long after the first charter of King Henry the Eighth was given

to the College of Physicians. If, indeed, a physician was employed, the apothecary, as is the case now, was considered as a subordinate person; but, in the absence of the physician, the care of the patient fell to the apothecary: in fact, as old Chaucer very decidedly intimates, they played into each other's hands:—

"For eche of them made other for to win,
Their friendship was not now to begin."

After Henry the Eighth had granted to the physicians valuable privileges and immunities, and they had greatly increased in number, disputes between the physicians and the apothecaries about the attendance upon patients gradually grew up; and the very measure which was proposed and carried out by Sir Theodore Mayerne and Dr. Atkins, through their influence with James the First, to separate the apothecaries from the grocers, and to constitute a Society of Pharmacopolites, as the royal grantor chose to denominate them, tended greatly to increase and encourage these disputes; so that at length the College of Physicians determined to establish by the strong arm of the law their sole right to practise, and to prevent any interference with their prerogative by the apothecaries. A case, therefore, was fixed upon for trying this important question. Mr. William Rose, a member of the Society of Apothecaries, was proceeded against for having visited John Seale, a butcher, in his illness; for having taken upon himself to judge of the disease, and for having sent him medicines without the advice and prescription of a physician. The jury, as is often the case now when anything appertaining to medicine comes before them, were puzzled, and, therefore, brought in a special verdict, "stating the charter, the confirmatory statute, and the facts of the case, and submitted to the court whether the defendant, Rose, did practise as a physician within the intent of the letters patent and the act of Parliament."

This special verdict was three several times argued before the judges, who came to the following conclusion:—

"That practising physic within this statute consisted 1, in judging of the disease and its nature from the constitution of the patient, and many other circumstances; 2, in judging of the fittest and properest remedy for the disease; 3, in directing or ordering the application of the remedy to the disease: and that the proper business of the apothecary is to make and compound and prepare the prescriptions of the doctor pursuant to his directions."

The judges, therefore, being unanimously of opinion that the facts proved against Rose did amount to the practising physic within the meaning of the act of Parliament, gave judgment accordingly.

When it is considered that, at the time when the judges came to this decision, the claims of the physicians to exclusive practice were advocated by most of the wits and literati of the metropolis; that one of the most fashionable of the poets, and an eminent physician, Garth, had not long before published a poem, "The Dispensary," in which the physicians were held up to the highest commendation, and the apothecaries to ridicule and contempt; when it is considered, also, how little attention, generally, lawyers (a) have given to physic: it is perhaps not to be wondered at that the learned judges came to this conclusion.

The Society of Apothecaries, however, were not to be daunted: they knew their own value and their own rights; they could not but know that they were not the ignorant persons which the Act of Henry the Eighth contemplated; they were not "common artificers, smiths, weavers, and women," but they were "persons skilled in the premises of this kind" whose duty it was

(a) The very delightful and talented author of "Passages from the Diary of a Deceased Physician," throughout his volumes, confounds the physician and the surgeon in a most extraordinary manner, and his *naïveté* upon the subject is most amusing.

"to search, view, and see such apothecary wares, drugs, and stuffs" as were used in the cure of diseases, and to the examination of which the College of Physicians themselves could not, under the Act of Henry the Eighth, proceed, till they had called to their assistance the wardens of the Apothecaries' Company. The master, wardens, and court of assistants, therefore, appeared by writ of error to the House of Lords against the verdict of the Court of King's Bench; and the Lords, "after hearing counsel on the writ, ordered and adjudged that the judgment given in the King's Bench for the president and college or commonalty of the Faculty in London should be reversed;" and thus the apothecary was restored to his old and legal rights, which have never since been called in question.

CHARACTERISTICS OF FEMALE BEAUTY.

[To the Editor of the Medical Times.]

SIR,—Having observed, a short time ago in your meritorious periodical, "The Arabian Estimate of Female Beauty," I have thought the following lines from Franciscus Corniger, on the same subject, a curiosity which might please some of your readers.

I am, Sir, your obedient servant,

LECTOR.

DE TRIGINTA NOTIS ELEGANTIE MULIERUM.

Triginta hæc habet, quæ vult formosa vocari
Femina: sic Helenam fama tuissæ refert.
Alba tria: et totidem nigra: et tria rubra puella:
Tres lineæ longæ res: totidemque breves:
Tres crassius: totidem graciles: tria stricte: tot ampla:
Sint talem luno formæ, sint quoque: pura tria
Alba cutis, nivi dentis, a buque capilli,
Nigri oculi, canine, nigra supercilia.
Labra, genæ atque ungues rubri: sit corpora longa,
Et longæ crines sit quoque longa manus.
Sint quæ inuice dentis, auris, pes, pectora lata.
Et clunes, distenti: et supercilia
Cunæ et os strictum, attingunt ubi cingula stricta.
Sint coarctæ culus, vulva, turgida.
Subtilis digiti, crines et labra puellæ,
Parvus ut naus, parva manilla, caput.
Cum nulli aut raro sint hæc: formosa vocari
Nulla puella potest, rara puella potest.

MEDICAL REPRESENTATIVES.

[To the Editor of the Medical Times.]

SIR,—The condition of the medical practitioner will, I fear, be but little improved until he can be fully represented in Parliament by a certain number of his professional brethren. The present niggardly manner in which medical men are remunerated for their important services to the sick poor is altogether absurd, the money they receive for such dangerous and arduous duties being scarcely sufficient to pay for the medicines they have to supply. The contract system appears to be a most unjust one, and so long as it continues the general practitioner will be inadequately paid for his services, and the poor but sparingly attended.

From amongst the great number of medical men in the kingdom, surely a few of them might be selected to sit in Parliament to forward the interests of the whole body. Many talented individuals would willingly accept a trust of such great importance to the whole medical community, and by discernment and eloquence they would soon raise the condition of their numerous brethren. The medical practitioner would then be better remunerated for his services, and he would also soon attain that position which, by his education, experience, and industry, he is so fairly entitled to.

** We agree with our correspondent.

THE ROYAL FREE HOSPITAL.

On Thursday, the 12th instant, an inquest was held at the workhouse of the Holborn Union, in Gray's-inn-road, on the body of William Benn,

who had died there on Saturday, August 7th. From the evidence of Mr. Simpson, it appeared that he had on the afternoon of Friday, the 6th instant, made application for relief at the Royal Free Hospital, whence he was sent unassisted, and, according to the witness, with some asperity. He then proceeded to the workhouse of the Holborn Union, falling twice by the way; and, on his arrival, was taken in, complaining of want and feebleness. At eleven o'clock the next morning he died.

Owing to the absence of some evidence judged necessary, the inquest was adjourned till Thursday, the 19th. On the evening of that day the inquest was resumed.

Mary Dale having been sworn said: I am a superintendent in the sick ward; on Friday, the 6th of August, the deceased was sent into the sick ward, between four and five o'clock in the afternoon. He said that he was very ill. I gave him a little gruel; he said he did not feel hungry, he wanted something, but did not know what. The quantity of gruel was a few spoonfuls. The doctor told me to give gruel. I gave him also a little tea. It was Plummer who gave me the doctor's order. He seemed so ill that I thought he would like to sleep. He could not feed himself, he was so ill. He stated that he had not slept in a bed for six months, and had been without tasting food for six days. He did not seem sick at all in the ward. He kept calling for medicine; his words were—"Oh, dear me, I wish I had some medicine!" I wiped the perspiration off him, which was very heavy, and he went to sleep. The pain of which he complained he said was in his stomach, and exclaimed, "Oh dear!" Mine is the only sick ward for the men; when they get better they go into the infirm ward. There were ten patients in my ward at once; at the time of Benn's admission the patients were all on fever diet; there were none in the ward who were receiving cordials of any kind. I had nothing beyond tea under my control which I could have given him. I did not think he was nearly so bad as he was, and did not inform the matron how ill he was. The deceased had had a bath, and patients are generally very much exhausted, so I did not wonder at him. I did not want to worry him, so left him to sleep. The doctor saw him in the afternoon, but did not come into the ward; no one came in but Plummer. I left at eight o'clock; at this time the medicine had not arrived; a man named Chickleday brought it, and gave it to Plummer, the night nurse. Chickleday was in the habit of bringing medicines between eight and nine in the evening. I gave him tea twice each time, about half a teacup-full. I got to the ward in the morning; a little after six o'clock; the poor man could not speak. I was told by the other patients that he had been making a bad noise all night. Plummer told me he thought he would not be here long. He said that he had administered medicine to deceased at about four in the morning, and that he had not spoken since.

It was here observed by a juror, that Plummer had stated that he had given some medicine to deceased at nine in the evening before, but none after that time.

Mary Dale's examination continued: I gave him more tea when I came in the morning; I poured it into his mouth, and it ran out at the corners; he could not speak, nor did he move his hands or make any sign. I did not immediately send for the doctor until Plummer thought he was dying; that was because I did not know the rule: there are no printed directions furnished to nurses, or placed in the ward; I depended on Plummer: he had been there all the night. The sisters of deceased have been here. They said that their brother was a dissipated, worthless fellow, and they would not attend the inquest. I went to his bedside every five minutes. About half-past ten Plummer turned him over on his side, and he expired soon afterwards. I did not see wine or brandy offered to him, nor was anything of the sort in the ward. Beef-tea was not ordered, nor put in the ward.

He died at eleven o'clock on Saturday morning. I noticed before he died that he perspired very much. He looked better when dying than when he was first brought into the ward. The doctor did not see him on Saturday before he died; he was expected every minute. Mr. Gibson came when he was dead, but made no remark. His assistant had seen him the day before. I believe he stated on his admission that he had come from Norwich.

A guardian, wishing to put a question to witness through the court, was informed that the inquest was not held for his gratification, but to further the ends of public justice, and that the inquiry would be as complete as any one could desire.

Benjamin Eagle, a witness at the former sitting, was here called. Mr. Gibson, the medical officer of the union, stated that he was too ill to be present. At his former examination he was very unwell, and the excitement of mind which that event induced had brought on a relapse. The shock had been very mischievous to him in his then state of health.

Mary Dale recalled: Eagle is in my ward in bed. He is very weak and in a fever. He has been very ill since the last inquest. He is taking medicine prescribed for him by the doctor, and lives on fever diet: fever diet is bread and water. I have not seen him to-day. Mr. Gibson has seen him every day.

John Rowland Gibson examined: I am a member of the Royal College of Surgeons, and one of the surgeons of this establishment. We have three departments: one of us has charge of the men, another of women, and a third of children of both sexes up to a certain age. I have the men under my care. I did not see deceased during his lifetime. I left between two and three on the day he was admitted. I did not hear of his illness, nor know anything of the facts, till I was informed the next day that he was dead, and that Mr. Jones had seen him. That was about the middle of the day. I have since then examined the body. I examined it on Wednesday, four days after death. I have not certified as to the cause of death. Mr. Jones did not speak to me of the cause of death. I did not know when Mr. Jones certified. I found decomposition was going on; the flesh was turning green, and air was forming in the cellular membrane. The body was thin, but not very emaciated. There were no external marks of violence, except a small mark on the forehead about the size of a shilling. The brain was of a healthy appearance; there was no engorgement of the vessels, external or internal; no congestion. On examining the chest, I found on the right side that the membrane lining the interior of the chest and that of the right lung adhered. The lobes of the right side of the lung adhered; there were old adhesions—signs of inflammation. Part of the lung on that side was puckered, hard, and had some deposit in it. Some of that deposit was undergoing softening. The greater part of that lung—five sixths, at least—was in a very engorged state; a very small part only was of a healthy character. The left side of the membrane lining the chest and that covering the lung adhered close, and was incapable of separation throughout its whole extent, except by force; that also was an old affection. The lung was almost converted into a substance of a fleshy nature—permitting very little air to enter, and presenting no appearance of a healthy lung. On the right side was some fluid of a dark-red colour effused into the chest, not bloody serum, but I think an exudation of the lung after death. The heart was large and flabby, its valves were sound. The stomach and intestines were distended with gas; the stomach contained about two table-spoonfuls, or an ounce. The intestines throughout were healthy. There was some fecal matter in both intestines, but small in quantity. The spleen was large and very engorged, offering a rather granular appearance. The right kidney appeared healthy; the left enlarged and softened.

Robert Plowright examined: I am porter at

the Aldersgate workhouse. A person, whom I believe was the deceased Benn, slept on the 3rd of August all night at the Aldersgate Union. According to our custom he was entered:—"Age fifty-four, of the parish of Guildford, dark complexion, hazel eyes, hump-backed, five feet eleven inches in height; is going to the hospital." He left on the morning of the 4th. He stated that he had some property. We gave him some supper on the evening of the 3rd, of pea-soup and five ounces of bread, and the same quantity of bread the next morning, with some gruel. He said when leaving, that he was going to the hospital, but did not particularize any one. He was dressed in a ragged surtout coat, light trousers, and old shoes; his clothes were very bad. He looked to me like a man who had seen better days. He left the union without complaining.

The Coroner doubted whether he stood so high as the individual described by Plowright. Mr. Gibson thought he was five feet ten inches. The rest of the description applied.

Owen Matthews, the undertaker, said he should think the coffin was about five feet ten; he did not measure the body.

George Farrow examined: I am gatekeeper and constable at the West London Union; I do not remember Benn; I have no entry of him. I have an entry of sixty-six persons who were admitted on Thursday night, but none of the entries answer to the description of Benn. I always ask, before any go out in the morning, if any one has any complaint. I always book the visits of the surgeons; we have a dispensary and medicines in the house. I cannot recognise the man by any part of the description that I have heard. We never refuse any at our union while we have room; we admit all. If any ask for food we give them bread; if nothing is asked nothing is given.

George Merner sworn: I am porter at the Royal Free Hospital gate. I well recollect Benn applying for admission on the 6th of August; he wanted to go into the hospital. I told him that we had no beds, that we were very sorry that many patients were presenting themselves whom we were obliged to deny. He went round into the waiting-room, and I saw no more of him at that time, but remained at my post till he came round again. I asked him what was his name and where he came from; he said he was a labourer, his name was Benn, and that he came from the West Smithfield Union and had been directed to come to the hospital. I said I am sorry, but we have no beds. He saw the doctor; he did not bring any paper; he said that the doctor told him they had no beds. The doctor, he said, had recommended him to go back to the union, or to St. Bartholomew's Hospital. Directly after he was gone a person called out, saying that the man who had just come out had laid down. That was after Dr. Marsden had seen him. I considered it my duty to go out to the man; I found him then lying down about three or four yards from the hospital gate. Several people were standing round him. I raised him to a sitting posture and said to him, "My good man, you had better go to the union as soon as you can, for you cannot stay here." He made no reply. I said, "If you cannot get up I will help you," and I set him on his legs, raising him by his arm and his collar. He supported himself by a stick. I said "The union is not far, they will take you in; tell them we have no beds." I watched him a little way along the pavement and then returned to my duties. No one made any remarks at the time in my hearing. I saw no more of him. There are several persons present who will witness to my conduct towards him, that it was kind and without harshness.

A Guardian here wished the court to inquire if it was true that there were no beds in the hospital in which the unfortunate man might have been placed?

The Coroner could not put the question. He knew what was his duty, and could not submit to receive instruction in it from any one; the inquiry would be searching.

Richard Gregory sworn: I am coachman to

Dr. Marsden, and live at 65, Lincoln's-inn-fields. I saw Benn come out of the Royal Free Hospital on the Friday afternoon; he came out at the side gate. No one spoke to him. I did not hear the porter speak to him when he came out. He went and sat down a few yards from the gate. He did not fall down. He did not speak; a female went and told the porter he was sitting down. The porter came and said "You must not sit here, you had better go down to the workhouse as fast you can." The porter took him by the right arm and one man assisted to raise him up. It was done quite carefully. I heard no one make any remark, nor did I hear Simpson say anything. I do not know Simpson. There were twelve or thirteen persons who came round him. Did not hear any such expression as "murderous conduct." I was at the time sitting on the coachbox. I did not see him fall. There was no violence used.

William Beattie sworn: I am a hearth-rug-maker. I was at the Royal Free Hospital as a patient on the day when the deceased made his application. I saw the man sit down outside the hospital, and saw the porter lift him up without any violence. He was raised up by his collar and right arm. I heard him advise the deceased to go to the workhouse as fast as he could, and told him the distance was not great. He used him as gently as possible. I did not hear Benn say anything in reply to Merner. I remained there two or three minutes after Benn was gone. I do not recollect Simpson. I heard some one say it was a pity that they did not take him in, he looked so bad. I went to the hospital on Tuesday, according to my habit as a patient, and then learned that an inquiry was on foot.

Dr. Worthington, incumbent of Trinity Church, Gray's-inn-lane, would like to ask a question.

The Coroner: Sit down, sir. If silence is not maintained I shall be compelled to interfere in a way that I should wish to avoid. I cannot allow these interruptions in my duty.

Dr. Worthington: I also have a duty.

Dr. William Marsden sworn: I live in Lincoln's-inn-fields, and am one of the medical officers of the Royal Free Hospital. On the 6th of August Benn applied for admission to that institution a little after three o'clock. I saw him in the surgeon's room, where I examine patients. I said to him, "What is the matter with you?" He replied, "I am very unwell, I want to get into the hospital. I slept in the workhouse last night and the night before, and have been in London several weeks. I felt his pulse and examined his tongue. I told him that he had heard me say to several patients that we had no beds at liberty, otherwise I would take him in; but, if he liked, I would prescribe for him, and he could have the medicine. He said, "It is of no use doing that, I want a bed and something to eat." I replied, "This is not a poorhouse, you must go to the union from whence you came." He said he had passed the over night at the Holborn Union, West-street, Smithfield. He made no remark or reply. I did not judge him to be labouring under acute disease. He appeared feeble, but not particularly so. I had at that time one hundred and twenty-three male applicants for admission into the hospital, besides females, and twenty-three wanted beds; we had no vacant beds at that time. It was a fact that we could not receive him. I do not know precisely how many patients we had. We have two large wards locked up, which have not been open for the last twelve months, in consequence of a diminution in the funds. The wards appropriated to patients were full. I had no other reason for not admitting him. I should certainly have done so, if I had had a bed, though I thought it not a hospital case, but rather more adapted to the poorhouse. It is a common thing for thirty or forty persons to come in one day and say that they are sent from unions, but they only want food. I am simply stating a fact, in saying this, and am not giving an opinion. The porter had instructions, before any patients came, that the hospital was full, and he only

performed his duty when he stated that fact to the applicants. The man, when so informed by the porter, insisted upon going forward, and presented himself with the other patients. It is a common question with me to these patients, "Where did you sleep last night?" We have been found fault with by the governors for receiving such cases as more properly should be sent to a union maintained by the parish, than to an institution supported by private donations for the relief of the sick. One nobleman had withdrawn his subscription on that ground, and a resolution was passed against admitting such. I ordered him no assistance at the hospital. It used to be a custom till within the last twelve-months to give relief, but since the falling off in the funds the governors have thought it best to draw in. Persons came, and we gave them money; and many came feigning disease, merely to get the donation. It is still continued in some cases; sometimes it is given in money; at other times in such a shape as seems fittest, as porter or other requisites. There are one hundred and forty beds in the hospital, and the wards were full at the time; there were more than thirty patients in the hospital: I should think between thirty and forty.

Dr. Worthington: And that in an hospital receiving an income of £9000 a year!

Merner recalled: I was not on Friday specially instructed that there were no beds; I had general orders to that effect, but was not to obstruct any one wishing to see the medical officers. There was no notice put up at the hospital gates that the beds were full. I sent those who came to the nearest union. I keep a list of names of those persons who represent that they are sent by officers of unions.

Dr. Marsden: I told him that if he could wait till the next day, and could come again, he should have the first bed. There was no unoccupied bed at the disposal of the medical officers. The institution is supported by voluntary contributions.

Merner recalled: I do not know whether or not any patient was admitted to the Royal Free Hospital on Friday: there might have been an accident, but I am not sure.

Elizabeth and Charlotte Benn, sisters of the deceased, were then called, but did not appear. The Foreman of the Jury then visited the witness Eagle in the sick ward, and, on his return, reported him too ill to attend.

Mr. Gibson was then recalled, and in answer to the question, "What was the cause of death?" replied, "Primarily, the organic disease under which he had for some time laboured; immediately, it was want of food and the other attentions which his state of health made needful."

The Court: We are here, Mr. Gibson, only dealing with the immediate cause. You have heard the evidence of the case; do you attribute his death to his non-admission to the Royal Free Hospital?

Mr. Gibson: Not especially to that source. I believe that if he had been received and relieved at an earlier period, and placed in suitable circumstances, he would not have died when he did; but I believe that, whatever treatment he might have received, his life could not have been much prolonged.

The Court: Do you believe that any treatment whatever, here or at the Royal Free Hospital could, have saved his life?

Mr. Gibson: For some little time.

The Court: The organic disease was in the lungs?

Mr. Gibson: Yes.

The Court: Could he have been restored to anything like health by any treatment which could have been employed?

Mr. Gibson: I believe not.

The Court: Do you, then, infer his death on the 7th August to natural disease, or to any other natural cause, or to the withholding of that assistance which his case required?

Mr. Gibson: I think one cannot be taken without the other. His first condition must be admitted before the second. Had he been in

a state of health the man would not have died from the privations which he experienced. The habits of intemperance, which, I think, were indicated had made inroads on his constitution.

The Court: The whole case is before you; the jury will have to form their verdict, and your testimony is most important. Please, therefore, to give a clear answer to my question. From what cause do you believe the deceased died on the 7th of August?

Mr. Gibson: I cannot answer that question in a more positive manner than I have already done.

The Court: I think we are under the obligation of finding the cause of food with the previous state of organic disease; the question is sound, and cannot make it simple. I visit daily the sick ward, and see all its inmates and inquire for them at the bedside; my order is that each

patient's copy, and a copy is passed on the bottle. In cases of emergency my practice has been to prepare the medicine and despatch some one with it immediately. The medical officer has at all times full power over the dietary; no presumptuous spirit of the guardians ever interferes with the full carrying out of the dietary orders given by the medical officers. Wine and beef-tea are given wherever necessary, and by the book it will be seen for what patients they are prescribed.

The Court: What are your arrangements with your assistant?

Mr. Gibson: I have no written arrangement with him; Mr. Jones has the same power of ordering what he thinks requisite as I have. I consider the treatment of the sick in this ward as under my control.

The Court: Whom then do you blame in this case?

Mr. Gibson: My assistant.

The Court: What are your instructions to him?

Mr. Gibson: His practice has been to attend in my absence, and in cases of emergency; and he has always had the power of doing what, in his judgment, the case required. He has been with me two years and a half.

The Court: You wish, Mr. Jones, to make any observation before the case goes to the jury?

Mr. Jones: I do not, Sir. I did not order the man wine or other cordials, because I thought he was not in a fit state to bear it.

Mr. Gibson said that the system was not to blame, for Mr. Jones might have freely ordered what was necessary, and it would have been given, whether it had been wine, beef-tea, or any other remedy he might have thought fit. We have had in the union eight gallons of wine within the last week. I have no doubt that the patients have had it. It is under the care of a most respectable woman; besides which, each patient has a statement of what is ordered for him pasted on his bottle, and they generally look sharp after the wine.

Thomas Heath examined: I live in Weston-street, Spalding; am by trade a smith, and was at the hospital in Grey's Inn-lane on Friday, the 6th of August; whilst I was waiting, the deceased came and sat for a quarter of an hour before the doctor came. I went in next to him, and was undoing my leg whilst the doctor was talking to him. The doctor said, "I cannot admit you, as I have no bed; I will administer to you as an out-patient, if you think proper." He said, "No, he wanted a bed." The doctor said, "If you will come to-morrow, I will take you in, if possible." I heard him say that he was eighty-three miles from home. I thought he was in a state of extreme destitution; he looked as though he was starving.

Mr. Gibson: I think it was a case that might have been admitted either at a hospital or a workhouse. Mr. Jones's attendance is sanctioned by the guardians and by the commissioners.

The Coroner then, charging the jury, said:—Gentlemen, this inquiry was instituted in consequence of a statement first made by the witness, Simpson, who was examined last Thursday.

He applied to me on the Tuesday following the poor man's death, making a statement which has been again made before you, relative to the non-admission of the deceased into the Royal Free Hospital, and his subsequent speedy death, from which I judged some inquiry to be necessary, and sent a constable to learn the particulars of the case. Simpson said, that on calling at the workhouse he ascertained that the body was about to be buried; but from the report of the constable I thought that a judicial inquiry was absolutely necessary; still it was not by any complaint, or any supposition, that anything had been done wrong in this house, that my mind was led to that conclusion. No complaint against any officers of this establishment was made, nor was it intimated to me that any neglect which had been shown to the deceased bore his death had been hastened. In all these cases, gentlemen, there are many difficulties to encounter with regard to the law, to evidence, and in tracing the facts of the case, and frequently they are too great to be entirely surmounted. In this case we have a very imperfect history of the man: from two o'clock on Friday afternoon to his death on Saturday morning, is the whole of the period respecting which we have any certain knowledge. Where he slept, and how he was dislodged, whether by force or otherwise, we do not know. I thought it might turn out that such had been the case; and it should be known and understood that distressed people have, by the law of the land, a right to relief as clear as the title of as any gentleman in England to the free and undisturbed possession and enjoyment of his estate; and therefore, heavy, indeed, is the responsibility of those who are intrusted with the execution and administration of that right, and woe be to him who withholds it from the needy. In this case the conduct of some approaches to that extremity; its history discloses the most painful facts—a picture of circumstances which we could hardly have believed would take place in a civilized country, and which we could never have anticipated from this inquiry. The first witness was Henry Simpson; he saw Benn on August 6, outside the hospital gate, lying on the bare stones, and groaning apparently in great pain; he did not then speak to him, which he explains by saying that he saw the porter take him up, and heard the porter say to him, "Come, old man, you must not stop here, you must go to the union where you came from;" he saw the porter raise him up, and, with the assistance of his stick, he walked on as far as Trinity Church; soon after witness saw him lying a second time on the stones. Witness was walking in the same direction, and said, "You had better let me assist you to the house;" and he succeeded in getting him up, and took him and gave him some ginger beer. The unhappy man said he had come from the country and had walked eighty miles, and had slept lately in various workhouses in London, and on Thursday night somewhere near Smithfield; he said that he had complained of illness at the workhouse, and that they had turned him out. Whether this was strictly true or not we have no means of ascertaining. He said, "I cannot die in the street. I am very ill." His eyes were sunk in his head, and he looked like a skeleton; he could not eat anything, but complained of thirst. The porter at this house said that he ought to have gone to St. Pancras Workhouse. Now, there exists in some minds certain jealous feelings with reference to the admission of the poor into public institutions; they appear to arise from the Law of Settlement, and I am afraid they will continue so long as the law remains in its present state; but we must deal with matters as we find them, and it is to be hoped that the day is not far distant when the restrictions and obstacles of that law will be got rid of. Two hours after the admission of the deceased, Simpson called at the house, and found that the doctor had been sent for, but had not arrived; no medical man had seen him; nothing had been given to him. On Tuesday Simpson called at the house, and was told that the doctor had seen him soon after witness had left on

Friday. It is admitted that the man did apply on Friday at the Royal Free Hospital, and that after he came out he lay, sat, or fell on the stones, and that he was picked up and set to walk, and that, about 150 yards farther on, he was seen on the stones again. These things all show his state when he applied at the hospital. Dr. Marsden saw him, and told him that the beds were full, but it seems incredible that a man in his condition should have been allowed to leave any public institution without receiving any relief. Neither money nor food, it appears, was offered to him. The public subscribe to that institution in the belief that there the hand of charity will be freely and instantly extended to all whose want and destitution require relief; and no statement that the beds were filled will satisfy any one that some simple and immediate relief might not have been offered. Such a course might have been somewhat out of the usual routine, but in such a case routine must be set at defiance—system is not to be maintained at the expense of the wants, and perhaps the life, of a fellow creature, but must bow to the emergency of the occasion. But nothing that may have taken place at the Royal Free Hospital can be held to excuse what is done at another place; each must stand on its own merits. I cannot, however, refrain from expressing my concern that no relief was given at the hospital when his condition might have indicated it to non-medical as well as professional observers. That such a man should be found in the street, in the middle of the day, within a few hours of death, is astounding. He was admitted here between two and three, and nothing is given him; the doctor is sent for when you would have expected that the cook would have been the proper person; but the doctor does not arrive until four; he ordered medicine for him, and left; and then Chickledy says that he went to the doctor in the evening, a few minutes before six, returning at half-past six; the medicine was not delivered till after eight; Plummer says not till nine. These statements have been made again and again, till there is no disputing them. Mr. Jones's statement was, that he examined the man, and considered that he was sinking fast, and that he considered the case hopeless. Other witnesses say that, although he looked very bad, they did not think he was so near death. Now, the man had walked here, and Mr. Jones considered it a hopeless case from inanition, yet he orders him a hot-bath! Why, it is a great exertion to go into a bath even to a man of strong constitution, and what must it be to a man so exhausted as this poor man was? He could not stand. Now, if Mr. Jones thought the case hopeless, why have him put in a bath? He should have known that such exertion left life hanging on a thread, and it might have killed him. The man tried to get to the sick ward, but could not; he was carried there between five and six o'clock in the evening. Nothing was given him but a few table-spoonfuls of gruel, and the tea which the woman gave to him. Mr. Jones thought his stomach was too irritable to bear anything, but the evidence says that he did not vomit at all. So that, if anything had been given, it would have sustained his system for a while; although, under the conditions described by Mr. Gibson, we cannot say how long. Mr. Gibson I know as a man of great worth and high character in his profession; he has described the system of the union to you, but you have now to do with the matter in hand, and not with the system. Mr. Gibson has not attempted to explain this most extraordinary omission; all we know is, that the man was brought here, and that from his first admission he did not receive those succours from the persons appointed to carry out the intentions of the law in this institution which he required. These are the main facts of the case, with the exception of Mr. Gibson's estimate of disease. It appears to me that an opinion existed in the mind of Mr. Jones, that the man was not in a state of disease, since he says he attributed his death to want of food,

--	---	---

COURSE OF LECTURES ON CLINICAL MEDICINE,

Delivered in the THEATRE of QUEEN'S COLLEGE, Birmingham.

By SAMUEL WRIGHT, M.D.,

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and Senior President, of the Royal Medical, Royal Physical, Hunterian Medical, and Oulverian Natural History Societies of Edinburgh, &c.

Case of erysipelas; details of; treatment; results; pathological character of erysipelas; how distinguished from erythema; how from phlegmon; erysipelas a contagious disease; illustrations of the spontaneous origin and communicability of this disease; observations thereon; remarks upon the treatment of erysipelas; general treatment the most important; necessity of varying this according to the degree of inflammation and the strength of the patient; danger of over-depletion; comments upon the case above narrated; local treatment of erysipelas; varieties; observations upon their relative value; conclusion of the course; terminating observations.

GENTLEMEN,—In my last lecture I promised you that its successor should chiefly embrace the subject of erysipelas, of which you saw an instructive example in the hospital a month ago. The sufferer was the poor fellow Baylies, whose death from epilepsy I recorded in my last communication with you.

Whilst under treatment for the disease that killed him, my attention was one morning directed to the seton at the back of his neck. The discharging surface and the contiguous structure, to the extent of eight or ten inches in circumference, had a very inflamed look. The secretion was much less than ordinary, and the pus thinner. The patient was thirsty and feverish, and had lost his appetite. Pulse 98, and firmer than usual; skin hot; tongue dry and furred; bowels moderately open.

The seton was removed, and the inflamed part covered with a large white-bread poultice, which was directed to be renewed every four hours. Cap. stat. hydrarg. chloridi, gr. v.

R. Sodæ bicarb., vini ipecac., aa. 3j.; tinct. hyocy., 3ij.; aquæ, 3viij. M. s. mist. cujus cap. cochl. amplâ duo tertius horis.

The next morning the patient was no better. The bowels had been several times well opened, but the thirst and fever were unabated. The tongue was still furred, and the skin hot, and the pulse firm and rapid. The poultice to be continued. To take with each dose of the mixture one of the following pills:—

R. Hydrarg. chloridi, gr. iij.; pulv. antimoniæ, gr. viij.; extr. hyecyami, q.s. ut ft. pil. viij.

The following day, July 8, he was much in the same general condition. There was less inflammation in and around the seton-mark, but it was now extending, with all the character-

istics of erysipelas, over the front of the neck and the lower part of the face. The poulticing was discontinued, and cloths dipped in cold vinegar and water applied to the inflamed parts. The medicines as before.

July 9. The fever still high, and the inflammation still spreading. Since yesterday it has extended over the whole face, which is swollen to nearly double its natural size. Vesications have appeared upon both ears, and upon the right side of the neck. The surface of the body generally is very hot and dry; urine scanty and high coloured; bowels open, but the abdomen is becoming tympanitic; pulse 112, firm and regular; tongue dry, red at its edges, and brown in the centre. Patient very restless, and wandering incessantly. The hair to be cut close, and the head kept moderately cool. *Contr. remedia.*

In the afternoon of this day there was little change, except that the abdomen had become more tympanitic. A turpentine enema was given, which occasioned a copious discharge of flatus, and some dark-coloured loose feces.

10. Patient much in the same state; fever still urgent; inflammation and swelling unabated; bowels open, and less tympanitic; kidneys rather more active. In the evening of this day, appearances were little altered, except that the patient was perfectly insensible. The abdomen was more tympanitic than in the morning; great restlessness; *subulitus*; there was perfect unconsciousness, but no abatement of the fever, and no tendency to sinking; the vesications were larger on the ears and neck, but the inflammation was as expressed as ever.

11. There was a very slight appearance of amendment, this morning. Desquamation was beginning to show itself in some parts of the neck; the face and head were less hot and swollen, and the redness was rather lighter; the bowels were open, and the tympany was comparatively inconsiderable; the kidneys were acting better, and the secretion depositing a lithate of ammonia sediment. Still the fever was high; pulse 100 and resistant of pressure; tongue quite dry, red at the tip and brown in the centre; there was less restlessness, but the patient could scarcely be roused to a state of temporary consciousness. The mixture to be continued, and a pill taken with every other dose.

In the evening of this day there were more decided signs of amendment. The tumefaction of the face was so much reduced that the patient

could partially open one eye, which he did when he shouted to and requested to make the effort. The inflammatory blush of the skin had still further diminished, and patches of desquamation were beginning to make their appearance in different parts of the face; the tongue was less brown in the centre, and slightly moist at its edges; the gums were rather tumefied, and there was a very faint mercurial odour in the breath; the surface of the body generally was softer, and seemingly inclined to perspiration; bowels open; urine tolerably plentiful; the pulse was under 100 per minute, but had still an undue firmness in it. The pills to be omitted; the mixture continued as before.

12. The patient still advancing, though slowly; more conscious than yesterday, but was very delirious in the night; no abdominal tenderness, and no tympany; bowels well open; urine copious and limpid; face less swollen, and desiccations spreading; tongue about the same, and aphthous spots appearing upon its edges; pulse less quick, but not reduced in strength. The mixture to be taken three times a day.

13. Improvement still more manifest this morning; patient slept well through the night, and perspired freely; tongue moist, but extensively studded with aphthous spots; bowels and kidneys acting well; pulse 80, soft and regular; patient quite sensible, though not very communicative; complains of no pain. To have beef-tea, with toast, three times a day.

R. Decocti cinchonæ, 3viij.; ammon. carb., 3ss. M. cap. cochl. largâ duo ter die.

14. Patient in every respect better; expression of face almost natural, except that the right eye is still closed; secretions healthy, and in sufficient quantity; strength somewhat improved, and appetite increasing. The amendment rapidly advanced, and on the 16th the patient was convalescent.

Erysipelas is simply an inflammation, commencing in the derma, and extending more or less into the subcutaneous areolar tissue. Its characteristics are, as you saw, pain, heat, redness, tumefaction, and desiccation or vesication. By the last, by its disposition to spread, and by its implication of the tissue subjacent to the skin, it is distinguished from erythema. It differs from phlegmonous inflammation chiefly in the tendency which the latter has to circumscribe itself, and to form an abscess. Sometimes, however, erysipelatous inflammation is productive of

purulent deposit: this is chiefly in places that abound with loose cellular tissue. In the case of Baylis, whilst the vesications were numerous upon his ears and the side of his face, pus was being formed under the right eye. It was subsequently discharged by puncture, and amounted in quantity to nearly two drachms.

Erysipelas is a communicable disease, and often has its origin in infection. Of course, however, it is capable of a spontaneous evolution. In the bed next the one wherein Baylis lay, a boy had erysipelas in one leg. I believe there were no local causes to account for it, and it appeared to be symptomatic, as it often is, of a bad state of general health. Before I was made acquainted with the proximity of my patient to such a source of danger, erysipelatos inflammation had seized upon the wound in his neck, and the consequences I have told you. In a short while, another patient in the same ward was attacked with the same ailment, and I began to be apprehensive that we should have it making the circuit of the hospital. The instances are many of a calamity like this, and of most disastrous results ensuing. By placing our patients, however, in a ward by themselves, we cut off all communication with the others, and thus happily limited the disease to the three cases I have mentioned. In these you have an instructive illustration of the origin and spread of this formidable affection. In the first instance the origin was constitutional, and the manifestation not very severe. In its simplest form, of which this was an example, erysipelas is seldom unmanageable. The boy was dyspeptic and debilitated, and the inflammation appeared in his leg: this is a part favourable to the mild progress of the disease, and to its localization. The subcutaneous areolar tissue here is not ample, and erysipelatos inflammation, in consequence, is seldom severe in it, or disposed to spread. From this boy, however, it passed to my patient, and acquired a character and an intensity from the very nature of the parts it seized. Commencing in the neck, and extending to the face, was a very different matter to being limited to one leg. In this second case, the parts implicated were extensive and vascular, thus giving every encouragement to the inflammatory action; whilst the contiguity of the brain made us apprehensive of its suffering from metastasis. From this patient it might have been communicated to another, and in him have acquired a phlegmonic character; whilst in a fourth subject it might have found an opportunity of showing its worst form, by terminating in gangrene. These several seizures might have been the occasion of other such, and the whole hospital, as I have said, have felt the consequences of the contagion. From small beginnings it is possible, you see, for the greatest calamities to arise. Happily we were afforded only a limited illustration of this well-known truth, but still quite sufficient to give you very distinctive evidence of the origin and progress of communicable disease.

The treatment of erysipelas is twofold—general and local. The former is the more important, because of the constitutional peculiarities which mark the severer forms of the disease. The peculiarities I allude to are strength of fever and violence of inflammation on the one hand; and depression, with tendency to sink, on the other. These not only call for opposite modes of treatment, but caution us also against letting either plan be excessive. By unduly sustaining and stimulating the cases marked by prostration and low febrile action, you may heighten this until an opposite treatment becomes necessary; but the strength of the patient forbids depletion, and there is a choice of evils—either to sink from the remedy or from the disease. On the contrary, in the robust inflammatory subject, if you bleed, purge, or in any wise deplete and depress largely and suddenly, he is likely either to be prostrated at once and to die without reaction; or to be so weakened as to be only capable of support by means which are pretty sure to bring a return of the inflammation and its consequences.

If the statistics of the lancet-treatment in erysipelas were before us, I think they would furnish some notable illustrations of "killing no murder." Mind, I am not saying that bleeding from the arm is never necessary in erysipelas. Often it is, and, when judiciously practiced, it is as often productive of the best effects. But, even when indicated in this disease, it should be employed with the greatest caution; there is no latitude to be given to heroic measures; the lurking tendency to sink, as I have said, should make you careful how you encourage it by over-debilitating. The old plan of treating all inflammations alike, has something homoeopical about it. Yet it has its advocates, for I had once the misfortune for some time to be a practical witness of the fact. I have seen patients bled for erysipelas as though they were suffering from peritonitis or pleurisy. I need not tell you that they died! The last melancholy case of this kind that occurred, to my knowledge, was in the person of a fine athletic young man who, after two or three days' disipation, was attacked with erysipelas in the neck. On the second day of its appearance, though it was neither severe nor threatening to spread far, yet, becoming alarmed, he sought advice, and submitted to a surgical remedy that soon arrested the inflammation. The poor fellow was profusely bled until he fainted; the reaction was the signal for *delirium tremens*, of which he died within three days.

The case of Baylis is a good illustration of the value of cautious treatment in erysipelas. It was a very formidable attack, and yet the patient recovered without desperate measures. The disease first showed itself on the suppurating surface of the seton: this was an irritable, highly vascular spot, that at once displayed the inflammatory action in its worst form. The discharge diminished directly, and ceased on the removal of the tape. Under ordinary circumstances, the sudden arrest of such a drain would be likely to be followed by determination of blood to the head: it would be the more likely, in this instance, because of the local inflammatory cause, and its subsequent extension. Here was at once a pathological probability in the distance which made the prognosis anything but favourable. The erysipelas spread rapidly over the neck and the face, involving both in one common inflammation, whose leading characteristic was intensity. This was the case we had to treat! The pulse, though firmer and more rapid than natural, as of course it would be, yet never acquired a very inflammatory character. At the commencement there was nothing in it, or in the patient's other symptoms, to indicate inflammation of the brain or of its membranes. These were my reasons for not ordering depletion at first. As I then told you, bleeding is so delicate a matter in erysipelas that I thought it better to wait for an unequivocal evidence of its necessity, than to anticipate this at the expense of the patient's strength and safety. After the subsidence of the more violent symptoms, the pulse retained a character that told of no extreme state. Less quick and less firm than at first, it had yet neither the sluggishly oppressive feel of cerebral congestion, nor the weakness and irregularity indicative of sinking. I made the pulse my guide throughout the attack; prepared to deplete if the state of the circulation demanded it, and to stimulate if depression should render this necessary. My own opinion inclined me to neither of these extremes; and therefore pursued a middle course. In the absence of more directly reducing means, the patient at the commencement had a smart mercurial purge, which brought away a considerable quantity of bile and feces, thus unloading the liver and preventing congestion, with its remote influences; and emptying the bowels of accumulated materials whose retention would no doubt have caused much sympathetic fever. The febrifuge mixture was constituted of materials calculated to allay gastro-intestinal irritation, to tranquilize the system, and act upon the skin. These were all desirable objects to be fulfilled, and I am not aware that I could have met them better than by

appropriate doses of soda, ipomeanha, and hyoscyamus. Small successive doses of calomel and antimonial powder were subsequently given to aid the action of the mixture, and to prepare the absorbent system for the removal of the products of inflammation, should any such be effused. Mercury is a very depressing agent, and the frequency of its exhibition was therefore diminished, proportionately to the subsidence of the inflammatory symptoms, until at last it was dispensed with altogether. This was all the general treatment during the acute stage of the disease, with the exception of the purgative enema, which was given to rouse the stolid intestines, and to divert from the brain, which seemed to be threatened with oppression. The local inflammation subsided before the pulse had lost its frequency and firmness; the persistence of the latter was the reason why I continued the febrifuge treatment after the erysipelatos condition had begun to disappear. So long as the pulse retained its unnatural force and quickness, we were not free from a liability to a return of the erysipelas, either in its original seat or elsewhere. Directly that the circulation gave signs of feebleness, bark and ammonia were given, and, as you know, with the happiest effects.

The local treatment of erysipelas is various, but not nearly of so much importance as the general treatment. Indeed, I have seen some very severe cases of erysipelas recover without the use of any local means whatever. Topical depletion is sometimes necessary. When this can be effected by scarification, it is preferable to leeching. It not unfrequently happens that each leech-bite becomes the centre of a severe inflammation, and that the erysipelas is aggravated in consequence. When the leeches have been unhealthy, they have occasioned mauling, and even gangrene. Flour, starch, magenta, rotten-stone, and other absorbent substances have been recommended to be applied to the inflamed surface. I have rarely seen them do any good. It is true, they defend the parts from atmospheric influence, and thus frequently relieve pain; but, at the same time, they prevent transpiration, which is the natural cooling process of the living surface, and a consequence is increase of heat, and not unfrequently of inflammation. Mercurial ointment, and other greasy applications, I think are worse than useless. Nitrate of silver is a favourite local remedy with some practitioners. I have certainly seen it check the spread of erysipelas most completely; but it is an unsmooth material to rub over a man's face. In the cases in which I have tried it, it has been quite as efficacious when drawn in a margin of half an inch broad just outside the erysipelatos blush, as when extended over the entire surface. Fomentations with hot water, or decoction of poppies, are often of excellent service. Whilst attending the case at the hospital, I was also attending a similar, though less severe, one, in consultation with Mr. Pye Chavasse. Additionally to mild mercurial and saline treatment, we ordered hot fomentations: the patient soon recovered. I generally, however, prefer these when there seems any tendency of the inflammation to leave the surface and visit deep-seated parts. In such cases the assiduous application of hot fomentations is often valuable. The cloths should be applied in constant succession, and care taken that a draught of cold air does not reach the parts directly after the removal of the cloths. A chill of this sort has sometimes been followed by great aggravation of the ailment. Pounded ice, and iced water, are occasionally used: they have been known to produce gangrene. I prefer water, or vinegar and water, of moderate coolness. This keeps the parts moist and the pores open, and absorbs the excessive heat gradually, without producing the sudden shock and collapse which are apt to follow the application of severer refrigerants. The cool cloths should be kept constantly on the inflamed surface, or strong reaction is apt to set in. Directly that they become warm, they should be

removed, and succeeded by others: the readiness with which this can be done, and the length of time that it can be continued, is another source of advantage possessed by cool over the wet applications.

This is my thirtieth clinical lecture, my last this season. In concluding, permit me to thank you for the polite and undeviating attention with which you have listened to my discourses. Much of their labour has been lessened by the gratifying manner in which you have invariably received them. It has been to me a source of the greatest pleasure to find that my occupancy of this chair has accorded with your own wishes; it will be equally agreeable to me to learn that I have not held it vainly, but have been honoured in the fact of having been useful to you as an instructor. At least, I can conscientiously say, that this has been my earnest desire throughout the delivery of the course now terminated. I commenced it, as you know, without any preparation; when I was far from being in good health, and when public and private professional obligations left me little

time for preparation. I am conscious of these facts, not ostentatiously, but as providing me with, I hope, an acceptable apology for various defects which have often marked the style and substance of my lectures. Had the time been permitted me for deliberating upon their arrangement and composition, I might have made them better worthy of your acceptance. But such has not been the case: more than once, indeed, I have had to occupy your time without having provided myself with a single note.

The cases which have been submitted to your consideration, with what commentary I have been capable of, I have taken from the general course of hospital business, only making selections when I have thought that, in so doing, I have been consulting your advantage. The time allotted to the clinical course did not give me the opportunity of treating so many topics as I could have wished; many instructive cases which have passed before me I have been obliged to omit from the list of those chosen for recapitulation and remark in the theatre of the college. Amongst them have been several valuable illustrations of diseases of the heart and lungs. Should the privilege be mine of a clinical instructor another year, it is my intention to confine my lectures to the above subjects. Important and complicated as they are, I shall perhaps better serve you by giving a course upon them exclusively, than by treating them variously with other less weighty topics.

And now, gentlemen, whether for a season or for ever, I bid you farewell. You have my best wishes for your health and welfare: at all times I shall be delighted to hear of your professional success, to which I shall ever feel happy and honoured in the opportunity of contributing.

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART XIII.

NERVOUS FORCE.—(Conclusion.)

Notwithstanding the great number of experiments made by the author respecting the phenomenon of induced contractions, he doubts the possibility of deducing from the facts revealed by these experiments a clear and definite physical theory of this phenomenon. He confines himself, accordingly, to a minute discussion of the several hypotheses that may be started to explain the phenomenon of induced contractions. We will content ourselves here to give the general conclusions at which he arrives.

1. The hypothesis which would explain the phenomenon of induced contractions by assuming that the electric current which excites the inducing contraction is propagated to the nerve of the galvanic couple, is altogether inadmissible; this hypothesis is simply and sufficiently disproved by the fact that induced contractions

are obtained equally in cases where the inducing contraction is excited by the application of any mechanical stimulus, instead of that of the electric current. We need not waste our time, therefore, with stating the many additional objections that might be urged against it.

2. The notion that the induced contraction is the effect of a mechanical stimulus—or, to speak with greater precision, of the contraction of one of the inducing muscles, which might be assumed to impart a mechanic shock to the galvanic couple—has been disproved experimentally by the author. Besides, how could we reconcile with this notion the cessation of the induced contraction occasioned by the interposition of a thin gold leaf or scale of mica between the nerve and the muscle?

3. It has been stated already that the author's first experiments led him to suppose that muscular contractions are attended with evolution of electricity. This assumption would, indeed, afford a very simple explanation of the phenomenon of induced contractions; but the results of subsequent experiments have, unfortunately, disproved it.

We are still ignorant as to the cause of muscular contraction; all that we know of this phenomenon may be summed up in the following propositions:—

1. Muscular contractions are induced by acting, even at a considerable distance from the muscle, upon the nerve spreading its ramifications to the latter.

2. The integrity of the nervous filament, from the excited point to the muscle, is indispensable.

3. The excitation is transmitted from the nerve to the muscle with a velocity comparable to that of electricity, light, radiant heat.

4. All causes that modify, promote, or prevent the manifestations of the physico-chemical phenomena occurring in the nutrition of the muscle, have an analogous action on the contractility of this organ.

5. The laws of muscular contraction present a certain analogy with the physical laws of elasticity.

Induced contraction may accordingly be looked upon as a phenomenon of induction attributable to that unknown force which circulates in the nerves and produces muscular contraction. It would seem more rational to term muscular induction what we have hitherto called induced contraction.

A muscle in contraction exercises an inductive action upon a living nerve.

In conclusion, a few words on the production of the nervous force. True, our knowledge of this force is confined to its manifestations in the living animal; yet, in our investigation into the mode of its production, we cannot altogether disregard physical analogies. Every manifestation, of any force whatsoever, is preceded by a transformation of matter, by a chemical action. Heat, electricity, light, furnish every instant proofs confirmatory of the correctness of this axiom. Even disregarding these analogies, let us examine the conditions in which the development of the nervous force takes place in the living animal. After long walks, or hard work, animals feel tired and require rest and food. Now, although we are without precise facts and data indispensable to establish an intimate and really scientific connection between the effects of labour, rest, and food on the one, and the loss and reparation of the nervous force on the other, yet we cannot abstain from discussing these facts, however complex they may be, upon the principles of mechanics and general physics. Muscular exercise, of whatever kind, is constantly attended with loss of force; and, as we see the animal machine recover its aptitude for exercise after feeding and rest, we are naturally led to assume that the force necessary for muscular action is derived from the chemical processes of nutrition. Interrupt for a certain time the circulation of blood in a muscle, and the latter will soon lose its contractility; with the return of the blood, the muscular force will reappear. In animals in which the circulation and respiration are very

active, the development of the muscular force is more considerable than in others of less active circulation and respiration.

But which of the numerous chemical actions occurring in the animal organism gives birth to the force that presides over muscular contraction? It is impossible to give a satisfactory reply to this question.

The physiologists of the present day admit that animal heat is produced by the combustion of fatty matters, and still more by that of the bodies into which the fecula is transformed in the process of digestion; whilst the production of the nervous force is attributed to the chemical actions occurring in the transformations suffered by the neutral nitrogenous substances of the tissues. We know, however, of no direct or experiment supplying a direct proof of this assumed difference of origin between animal heat and the nervous force.

Of all the chemical actions occurring in the animal organism, the only one which we know perfectly and are able to measure, is that which produces carbonic acid. On an average, an adult converts into, and exhales in the form of, carbonic acid from ten to fifteen grammes of carbon per hour.

Starting from these data, we may endeavour to compare the nervous force resulting from this chemical action—taking as the expression of this force the mechanical labour accomplished by an adult in the space of one day—with the amount of labour which the same action is capable of producing either by the agency of the heat, or by that of the electricity evolved by it. In other terms, we may ascertain whether we obtain with steam-engines or electro-magnetic apparatus, and by means of a certain fixed and definite chemical action, a mechanic effect equal to, or differing from, that produced by the same action working in the animal organism.

But, before we can enter upon this inquiry, we must admit either one or the other of the two following hypotheses:—We know that the animal organism evolves heat, electricity, and the nervous force; and we admit that the causes producing these forces reside in the chemical processes of nutrition. Now, we may suppose either that a certain chemical action produces constant, invariable, and distinct quantities respectively of heat, electricity, and nervous force, which quantities are altogether independent of one another; or that it produces invariably a constant amount of force without any regard to the form in which that force manifests itself.

The following illustration may serve to render these propositions more clearly intelligible. The combustion of zinc in oxygen produces light and heat: the oxidation of the same metal, by the decomposition of water, gives rise to the evolution of heat alone, or of heat and electricity if the metal is touched with platinum wire. Now, let us suppose we could transform these respective forces into a certain amount of mechanic labour produced by them: it might be assumed in that case that the sum total of the respective amounts is invariably the same, and that where one of the two forces fails to be evolved, the other is evolved in a proportionally higher degree, and supplies thus the deficiency; but it might be assumed, likewise, that the respective forces are evolved independently of one another. The latter supposition would seem to be borne out by the results of certain experiments made by the author: he measured the amount of heat disengaged in the oxidation of zinc by the decomposition of water, and found it constantly the same with that of the heat evolved in conjunction with electricity, and very nearly the same as that of the heat evolved in conjunction with light (in the other processes of oxidation of zinc).

We may, accordingly, reckon the whole of the chemical action of the combustion of the carbon in the animal organism as productive of the nervous force, independently of the heat and electricity which this action may produce besides; and we may then inquire whether this when taking place in the animal or-

ganism, produces effects analogous to, or differing from, those which it would produce if taking place in a steam-engine, or an electro-magnetic apparatus.

The author was once travelling with the celebrated engineer, Robert Stephenson. The travellers had occasion to ascend an individual to a distance of about forty miles, which he accomplished in about a day and a half, his march, consuming about 100 grammes of coal. The author, however, from Mr. Stephenson that it would take about five kilogrammes of coal to transport an individual the same distance with a locomotive.

Dumas has calculated the amount of coal which a steam-engine would consume to carry a man from the level of the sea to the summit of Mont Blanc. He calculated this amount from 1000 to 1200 grammes. A man can climb to the summit of the same mountain in two days' time, consuming thus only 300 grammes of carbon. The difference in this latter instance is less marked than in the former, because the power obtained from a fixed steam-engine is much more considerable than that yielded by the engines of a locomotive; this much, however, is evident, that the difference is still very great, and that the nervous force evolved by a certain chemical action, in the organism effects a much larger amount of labour than is effected by the conversion of the same action into heat.

The great advantage that results from the transformation of a chemical action in the animal into nervous force is evident also from the results of the following experiment made by the author:—

He measured the amount of mechanical labour obtained by applying to the nerves of a frog a current engendered by a definite amount of zinc oxidizing in a pile; the resulting numbers were as follows:—Three milligrammes of zinc oxidizing in one day supply a current which, supposing it possible to apply it constantly and uninterruptedly to the nerves of a frog, would produce a muscular force measured by 5.6419 kilogrammes raised one metre in the same space of time. These figures are, probably, inexact; but the sources of error in the author's experiments are all one way, viz., tending to underrate the effect produced by the oxidation of the three milligrammes of zinc.

The combustion of the same quantity of zinc would yield an amount of heat such as, employed to generate steam, would execute an amount of labour equivalent to 830.4 grammes raised one metre.

Finally, applying the current produced by the combustion of three milligrammes of zinc to an electro-magnetic machine, the power obtained is — 960 grammes raised one metre.

We are accordingly led to conclude that the mechanical power produced by a chemical action transformed into nervous force in an animal is very considerable, and that all the inventions of man, however ingenious, fall still very short of that degree of perfection which is observed in the machines constructed by nature.

THE BEES AND THE HEDGEHOG.—A gentleman in this neighbourhood had a tame hedgehog in his garden, which, in seeking his food, was at the same time a promoter of horticulture, by destroying many noxious insects. One day lately he unluckily went near a hive of bees, and a number of them attacked him with great fury; he defended himself by standing on his hind feet and striking with his fore paws. Finding, however, that the bees were getting the best of it, he coiled himself up in his bristly armour, but in doing so enclosed some of his enemies, who stung him severely. He then unrolled himself and renewed the fight for some time, but eventually retreated into a bush. Next morning the poor hedgehog was found dead, showing that, however completely the stomachs of these animals can resist poison, they are not proof against its external application, in the shape of the smarting sting of the bee.—*Dumfries Courier.*

STATISTICS OF MIDWIFERY.

By D. LEWIS, M.D.

Member of the Royal College of Physicians, London; and Physician to the Islington Dispensary.

During a connection of fifteen years with the Royal Maternity Charity, for delivering poor married women at their own homes, I have carefully collated from the midwives' books the following account of cases that were attended by them.

I have given each hundred separately, so that it may serve as an index to every practitioner in midwifery, however limited his practice.

The following twenty thousand cases are taken from the humblest classes of society, viz., the working classes—poor married women delivered at their own homes, and often in want of the common necessities of life; yet the average mortality and difficult labours will be found to be less amongst the poor than the rich, who are too often pampered with luxuries incompatible with the operations of nature.

The statistical table was constructed about four years ago, but owing to my absence from England I had no opportunity of publishing it.

23, Finsbury-place, Aug. 16.

ROYAL BERKSHIRE HOSPITAL.

SURGICAL REPORTS AND OBSERVATIONS.

By F. M. SULLY, Esq., F.R.C.S., Surgeon to the Hospital.

PARTIAL CLOSURE OF THE JAW, WITH RIGID CONTRACTION OF TWO LATERAL MASSETER MUSCLES, CURED BY MECHANICAL EXTENSION.

George S., a blacksmith, admitted Dec. 3, 1844, on account of a partial closure of the lower jaw, which had existed rather more than a fortnight. He is unable by his own efforts to separate the jaws to a greater distance than each other than about a quarter of an inch, and day by day he finds the difficulty is increasing. There is a feeling of hardness and swelling of the bone extending from its angle forwards for about two inches, this swelling having been nearly twice as large as it is at present; he has suffered considerable pain at this part, but is now comparatively easy through the use of leeches and blistering, which have relieved the pain and subdued the swelling. The masseter muscle on the same side feels hardened and contracted, and very painful, especially when slightly put upon the stretch in endeavouring to separate the jaws; the articulation of the jaw is apparently unaffected by the disease, the lateral movements being free, and performed without any uneasiness in the joint.

He states that he was employed in shoeing a vicious horse, which bit him and threw him down, and in some way struck him on the face, but in what exact manner, from the suddenness of the movement, he is unable to recollect.

The treatment consisted at first of such means as were calculated to diminish the pain and swelling of the jaw, such as the application of leeches and small blisters, which, after a short time, relieved these symptoms. The jaw remaining partially closed, and the masseter muscle continuing in the same hardened, contracted state, after the disappearance of the swelling it was deemed expedient to attempt to separate the jaws by gradual mechanical extension; and an instrument with two wide blades, capable of being nicely regulated by the action of a screw, was contrived for that purpose.

At first very little progress was made, and for some days I could scarcely observe that any further perceptible separation had been effected, being, moreover, obliged to use the instrument but for very short periods at a time, on account of the pain produced by the stretching of the masseter muscle; as he got accustomed to the operation, however, and could bear it longer, I could observe that, day by day, the distance between the jaws became increased, until at length he was able to open his mouth to its fullest extent without difficulty, and masticate his food as well as before the accident; and, at the end of the month from the commencement of the mechanical treatment, he left the hospital quite cured, and I have every reason to believe he has remained well ever since. The extension, which was applied daily, usually occupied from twenty to thirty minutes at a time, gradually increasing the force during its application, the blades of the dilator being covered with India-rubber sheeting, to prevent injury to the teeth.

COMPLETE CLOSURE OF THE JAWS, WITH RIGID CONTRACTION OF THE MASSETER, CURED BY MECHANICAL EXTENSION AND THE APPLICATION OF ELECTRO-GALVANISM.

John H., aged thirty-five, labourer, was admitted as an out-patient June 28, on account of a fixed closure of the jaws, which had existed about eight days before he came to the hospital. The jaws were firmly locked together, and could not by any ordinary means be separated from each other, the only interval between them being occasioned by his being naturally rather underhung, which had allowed of small quantities of

liquid food being passed upwards into the mouth; the separation, however, in this direction was so slight that he preferred taking what little sustenance he had been able to take through some spaces left by the decay of one or two of the molar teeth in the lower jaw, which he accomplished by passing the bowl of a small teaspoon within the cheek, and, turning aside his head, thus allowed the liquid it contained to flow into his mouth. He complained of extreme general weakness, from insufficient nourishment, not having tasted animal food of any kind for several days, and he had also latterly become very thin. On examination the masseter muscle on the left side of the face was found to be rigidly contracted, and of almost cartilaginous hardness, having all the characteristics of a muscle affected with tetanic spasm. Apparently no other muscle of the face was similarly affected. Occasionally he had felt great pain in the affected muscle, especially after using his own efforts to open the jaw.

He gave me the following account of the origin and progress of his complaint:—He had been engaged, with a number of other men, in placing carriages on Ascot-heath race-course, on June 2, when the pole of one which he was assisting accidentally swung round, and struck him on the side of the face; he was slightly stupified by the blow, but quickly recovered himself, and, beyond a slight stiffness of the part, experienced little or no inconvenience for three or four days; when, in returning home after the races were over, he got wet, and caught a severe cold, attended with great hoarseness, which continued about a week, during which time he felt but little of the jaw, with the exception of a trifling difficulty in masticating his food. At the end of that time, however, the hoarseness, which had been so great as almost to deprive him of speech, disappeared, and the stiffness of the jaw began to increase, so that he now felt a real difficulty in mastication; this difficulty increasing day by day, until at last the jaws became so firmly set together that he could not by any means separate them from each other. During this period the pain in the cheek, although not very severe, was constant, and was increased by pressing or pinching the contracted masseter muscle.

He had continued in this state during the ten days prior to the commencement of this report. The treatment immediately adopted was, the gradual separation of the jaws by means of the same apparatus as had been used in the other case; the thin blades of the instrument having been with some difficulty introduced between the teeth, a moderate extension was continued for nearly half an hour, at the end of which time, by very gradually increasing the force, the jaws had become separated to the extent of five-sixteenths of an inch. In the afternoon, electro-galvanic currents of moderate intensity were directed through the contracted masseter by placing one of the sponge conductors in the mouth underneath the muscle, and the other opposite to it outside the cheek. The operation of the electro-galvanism appeared of itself to produce some slight benefit to the part, as, without any force, the jaws could be separated about one-sixteenth part of an inch further than before it was applied.

29. The electro-galvanism was repeated, together with the use of the dilator, continued for twenty-five minutes; the extension occasioned some little pain in the contracted muscle, especially in that portion nearest the zygoma, which the galvanism seemed to relieve.

30. A separation of seven-sixteenths of an inch has been gained by a continuance of the treatment.

July 2. He can separate the jaws by his own muscular efforts to the extent of half an inch, and can now manage to drink a considerable quantity of fluid without inconvenience, and masticate small-sized pieces of food. He is beginning to regain his strength.

3. The extension to-day produced a separation of five-eighths, or more than half an inch; it was attended, however, with considerable pain, which was relieved, as before, by the application of the electro-galvanism.

7. The mechanical separation of the jaws has been daily practised, as well as the electro-galvanism, with a trifling improvement.

10. No improvement, from his having taken cold through working late at night in his garden. To have a stimulating liniment rubbed into the affected side of the face twice a day.

12. Complains of the affected side of the face feeling very stiff and uncomfortable, which he attributes to the use of the liniment. To discontinue the liniment.

15. The mechanical and other means have been continued; he can now by his own efforts separate the jaws to the extent of three-fourths of an inch.

27. Scarcely any improvement having taken place within the last few days, and as the poor fellow was daily losing strength from want of sufficient food, he was admitted as an in-patient of the hospital, the same means being employed as had been perseveringly used during the whole previous period of the treatment. To have extra diet, and a pint of porter daily.

29. Complained of a more than usual stiffness of the jaw, as well as for the first time in the thighs and legs, which he described as being affected with a curious crampy feeling. Fearing that he might become, even at this remote period, the subject of general tetanus, I had him placed in a hot salt-water bath, from which he appeared to derive almost immediate relief.

30. The warm-bath has entirely relieved the pains. No uneasiness about the jaw.

Aug. 2. A slight return of the crampy sensations in the limbs. To repeat the hot-bath.

6. The mechanical separation of the jaws has been daily practised since his admission into the hospital, and, as he could now easily separate them by his own efforts to the extent of an inch and a quarter, it was judged expedient to discontinue the use of the dilator, leaving the remainder of the treatment entirely to the electro-galvanism.

14. The masseter muscle on the affected side has nearly recovered its natural softness and extensibility, and there appears to be very little difference in its action from the other; he can now masticate his food without difficulty, opening and shutting the mouth almost with the same ease as before the accident.

21. Discharge cured.

Observations.—It has been remarked by Pro-

fessor Fergusson, that examples of permanent contraction of the masseter muscle, independent of any tetanic affection, are not often met with in practice. He had met with several instances of permanent inability to open the mouth to such an extent as to permit the patient to masticate, but could not say that his attention had been particularly attracted by the rigidity of any particular muscle. In such a case he had successfully practised the subcutaneous section of the masseter, (a) a proceeding which, in such able hands, might be easily accomplished, but which would not be without its difficulty and hazard to ordinary operators; it was with a view, therefore, to obviate the necessity for such an operation that I undertook in these two cases the separation of the jaws by the gradual and careful employment of mechanism.

It will be observed that in the case last related I employed electro-galvanism simultaneously with the mechanical extension; and I could not but remark its value as a remedial agent, more especially in relieving the pain produced by the stretching, which on each occasion it appeared to do, and thus enabled the patient to bear a greater amount of extension at a time, and its more frequent employment, than he might otherwise have been able to have done; its influence, also, in assisting the relaxation of the contracted muscle, when used without the extension, was so obvious that I should not hesitate, in any future case of general tetanus, in giving a more extended application of it the preference in the treatment to any other means with which I am at present acquainted.

Had I been acquainted with the power of this agent in mitigating the pain produced by the extension, and practised it in the first of these cases, I feel satisfied that the cure would have been performed in much less time than it occupied without it, and with much less inconvenience to the patient.

The dilator, which would doubtless be equally useful in all cases where a simple but powerful speculum-oris was required, may be obtained of Messrs. Weiss, surgical instrument-makers in the Strand, as constructed after the model of the one used in the foregoing cases.

(a) Vide "Provincial Med. and Surg. Journal" for Jan. 20, 1842.

INSTRUMENT USED IN THE CASES OF JAW CONTRACTURE.

Flat surface of the blade of the full size.

Side view of the dilator diminished. The cross bar A revolves upon the central screw, and is provided with a deep square notch at each end, in which the branches work. This bar being made to approach the point at B, by turning the central screw, the branches are separated from each other by a very powerful leverage.

THE PHYSIOGNOMY OF DISEASES OR SEMEIOTICS IN THEIR ASSIMILATIVE CHARACTERS.

By GEORGE CORFE (Author of "A Popular Treatise on the Kidney," &c.), of the Middlesex Hospital.

[Illustrated by Portraits of Cases.]

(Continued from p. 433.)

The most severe lacerations and injuries to which the human frame can be liable are found in our hospital surgeries: some of them, most trifling to appearance, ending in death; and others, of the severest form, rallying and healing up under the mode of treatment prescribed.

These are facts as incontrovertible as they are extraordinary, and tend to show us that God is indeed the Supreme Governor of nations, thrones, and individuals; of life, of health, and of death.

The study of physiognomy was much attended to amongst the Greeks and ancient philosophers, but was not revived until the middle ages. (a) Baptista Porta, a physiognomist of great eminence, wrote a treatise "On the Physiognomy of Plants and of Birds." The "Maga Physiognomica" of Gaspar Schottus, the work of Boyle, and lastly, the elaborate treatise of that singularly gifted author, Lavater, have reduced the subject to some definite and scientific principles.

Haller thus expresses himself:—"It is the will of God, the great author of society, that the affections of the mind should express themselves by the voice, the gestures, but especially by the countenance. Nor is this species of language wholly denied even to the brute creation. They, too, by signs, express their love of kind, social friendship, maternal affection, rage, joy, grief, fear, and all the more violent emotions. A dog easily discovers whether you are angry with him, by your face and tone of voice. The bellowing of the bull, and the roaring of the lion, are indicative language, too well understood to be controverted. I shall say little of sound, though it

(a) Aristotle formerly treated of the subject, and states that a peculiar form of body is invariably accompanied with a peculiar disposition of the mind, and a human intellect is never found in the corporeal frame of a beast. As a lion, by his strong hair, deep voice, and large extremities, exhibits his amazing powers of body; and the hare betrays its pusillanimity by its slender extremities, soft down, and other features. So the character of a vigorous mind and that of a feeble mind, are respectively seen in the corporeal frame of man.

is undeniably certain that every affection has a tone peculiar to itself." (a)

But the physiognomy of countenance in health has been most ably treated of by Lavater, who asks, "Does the human face—that mirror of the Deity, that masterpiece of the visible creation—present no appearance of cause and effect, no relation between the external and the internal, the visible and the invisible, the cause and what it produces? Would not common sense revolt against the absurdity of maintaining that a robust man may have a perfect resemblance to one infirm, a person in full health to one dying of a consumption, a man of an ardent character to one of a sedate and gentle disposition?" He, too, was not insensible to the amazing advantages that were to be obtained from a study of the physiognomy under diseases. As to the physician, he remarks, the physiognomy of the patient frequently instructs him better than all the verbal information he can receive. It is astonishing how far physicians have carried their sagacity in this respect. "I shall be told," says another writer, "that physiognomy is often deceitful. Yes, it is possible to counterfeit, but the apparent constraint generally betrays the imposture; and it is as easy to distinguish a natural

from an assumed air, as a thought that is just from one that is brilliant. Paint laid on, however dexterously, is never the skin itself. I am not in the least staggered by the objection that a fair outside may cover a corrupted heart." (a)

"What would medicine be without the knowledge of symptoms, and what were symptomatical knowledge without physiognomy? and just as a man does not become a professed politician by reading Grotius and Puffendorf, so a physician does not become skilful by attending Boerhaave's lectures. Whoever thought of advancing objections against the doctrine of diversities of diseases? Was he to that physician who, without employing physiological or pathological physiognomy—who, without consulting in every particular case his physiognomical sentiment—should tie himself down to treat every disease according to its specific class, without once thinking to modify his prescriptions in conformity to the peculiar symptoms which he observes in his patient. Rank, condition, habit, estate, dress—all concur to the modification of man; every one is a several veil spread over him. But to pierce through all these coverings into his real character—to discover in these foreign and contingent determinations, solid and fixed principles by which to settle what man really is—this appears extremely difficult, if not impossible." True, this is the sole prerogative of Him whose eye can alone search the heart and know the inward workings of its interminable labyrinths. "It is true man is acted upon by everything around him, but he, in his turn, acts upon all these external objects, and, if he receives their impression, he also communicates his own. Hence it is that a judgment may be formed of a man's character from his dress, his house, his furniture. Nature forms us, but we transform her work, and this very metamorphosis becomes a second nature. All faces, all forms, all created beings, differ from one another, not only with respect to their class, their genus, their species, but also with respect to their individuality."—*Lavater, by D. Hunter, vol. 1, 1798.*

Having thrown out a few introductory remarks, I now proceed to a closer view of the subject proposed, namely, a brief dissertation on "The Physiognomy of Diseases in their Assimilative Characters." It is a wide field, after all: nevertheless we can particularize and portray individuals of the copper-coloured Indian race, of the black-skinned African, or the tawny Chinese; so we may try to trace the lineaments of disease generally, and of some in particular; though the species present the like features often, yet in nature, character, and end, they vary in the greatest degree. If it were not true that divers diseases are seen to present similar symptoms in one stage or other of their progress, whence would come the difficulties which start up, and which are weighed with such care and intense anxiety by the judicious and skilful medical man? The object, therefore, of these considerations is to bring forward the assimilation or likeness—certainly not family likeness—of diseases to each other: for though they are not in any respect akin to each other, but in the general name, disease, as one inhabitant of the earth is no relation to his antipodes, excepting in the general term man, yet the portraying of these varied lineaments of disease, which assimilate in a general character, may open the path a little wider to, and thus facilitate, the clinical student in his studies of internal diseases.

On rushing into a rich flower garden, we are bewildered with profuse abundance, dazzled by countless specimens, and distracted by splendid variety; and perhaps the bouquet, afterwards gathered, may consist of the commonest and least odoriferous productions of the crowded parterres; so with myself, as I turn a retrograde step into the scenes of our wards, and try to cull from memory's precincts a store of rich and interesting facts to illustrate the theory I have taken up, I feel bewildered with numbers, and distracted with immense variety. It is very possible, that

that I may select the least interesting from the thousands of our physicians' cases which I have had under my care; however, whatever be their value as examples, they are correct as portraits, and I trust will be closely enough applied to illustrate my meaning. Thus the very mass of material which some artificers are required to build from is the chief impediment in the raising of their edifice.

So close is the knitted texture of head and body, that it is a rare occurrence to be enabled to designate a disease purely cerebral, or wholly thoracic. A man may rupture a cerebral artery from mental or bodily exertion; he may have pneumonia from a sudden chill of his body, and so forth; but as the disease, no matter from what origin, is concentrated in the brain, or in the lungs, and as the chief symptoms seem to converge to that part, so we give the name of the disease to the distress in that organ, especially in the terms "apoplexy with oppressed breathing," or "pneumonia with delirium," &c. &c. This being premised, the classification of the higher diseases, according to their physiognomy in the first glance of the eye, will be readily admitted.

The whole man, indeed, sympathizes in an ache or a pain in any part of the bodily frame; but such sympathy is far greater in some organs than in others. Man is a dependent creature; and, speaking in deep submission to the One eternal Great Cause, there is an unceasing mutual dependence upon the action and perfect play of every vital performer of the vast orchestra of the bodily powers:—

"Strange that a harp of thousand strings
Should last in tune so long!"

says the pious Dr. Watts. Yes; and one little discordant tone here is enough to spoil the whole harmony.

The subject, then, seems to admit of the following arrangement as a sketch of the "Physiognomy of Diseases in their Assimilative Characters."

CLASS I.

Division I. *Cerebral Diseases in Insensibility; Countenance lethargic.*

From Apoplexy.
Ramollissement.
Otitis, &c.
Tumours.
Arachnitis.
Injuries of the head.

Division II. *Cerebral Asphyxia in Stupor; Countenance livid.*

From Narcotic poisons.
Coma.
Hepatic disorders.
Renal degeneration.
Intoxication.
Syncope (hemorrhagic).
Facial paralysis.

Division III. *Cerebral Sympathies in Irrationality; Countenance distressed.*

From Delirium tremens.
Paralysis agitata.
Paralysis venena.
Hysteria.
Mania.
Epilepsy.
Chorea.
Pericarditis.
Pneumonia.
Enteritis.
Fever.

CLASS II.

Division I. *Thoracic Derangement; Countenance dusky.*

From Pneumonia.
Pleuro-pneumonia.
Pneumonic engorgement.
Oedema pulmonum.
Asthma.
Bronchitis.
Endo-carditis.

Division II. *Thoracic Derangement; Countenance anæmic.*

From Laryngitis.
Tracheitis.
System of Nephritis.

(a) "Haller. Elementa Physiologica," t. 5, p. 590. There is a curious and most interesting work bearing upon this subject, by Dr. Gardner, "The Music of Nature," in which he elucidates the various cries, howlings, calls, and moanings, &c., of the brute creation.

"Who has not recognised the plaintive tones of the mateless wood-pigeon and turtle cooing for its return, whilst passing by the thick woods after sunset? Who cannot recognise the difference between the sorrowful howl of a faithful dog which has lost his master, and the fierce bark of another which has been alarmed by some stranger? Every one is familiar, too, with the common cluck, special cluck, and alarm cluck of the fostering hen. Truly the subject is a wide and pleasant field to wander into, but I must not digress further, but would observe only, that even the position of the eye, nose, and ear in various animals, proves the truth of physiognomy as a science. Take the latter organ as an example. In timid creatures, as the sheep, the feline class, and those which are pursued, as the hare, rabbit, &c., and ruminants in general, this organ is inclined backwards towards the direction from which the sound of their pursuer proceeds, whilst at the same time, being so very movable, it may be thrown so flat upon the head and neck as not to impede the rapidity of their flight. This may be noticed in that noble creature the horse. Who has not seen the downcast ears of the jaded cab horses in London, as they pass along, kept in one constant state of terror by the gnarling driver, and the fear of the too oft-applied lash to its emaciated sides? and who has not observed the favourite cat, seated at the fire-side, knowingly throw one ear back towards the door, to gather up the strange sounds of some approaching but unfamiliar step?

"Sir H. Davy observed, that dogs when blind-folded have the power of finding their way by the sense of smell; every lane, field, or town has its particular smell.

"Dr. Darwin, in his 'Zoonomia,' remarks, that if a string of horses is noticed upon travel, you will find that the first horse points his ears forward, and the last behind him, keeping watch; but the intermediate ones, who seem not to be called upon to do this duty, appear careless and perfectly at their ease.

"A dog, belonging to a change-ringer, used to accompany his master to the belfry of St. Martin's Church, in Leicester; and upon commencing a peal of changes he would lay himself quietly down, and not attempt to stir till the bells began to 'ring round,' which intimated the finishing of the peal, and which he always noticed. He would then get up, shake himself, and prepare to be off from an amusement for which he had less relish than his

Pleurodynia.
Pleuritis.

CLASS III.

Adrenal Scissures; Countenance pinched.
From Colic.
Colica pictorum.
Gallstones.
Urinary ditto.
Spasm of gall-bladder.

Constipation,
Intussusception.
Hernia.
Ascites.
Peritonitis.

" hysterical.
" true.

CLASS IV.

Division I. Emaciation of Frame, &c.; Countenance wan.
From Tubercular disease.
Cancer Stomach.
" uterus.
" rectum.
" mammae.
Hemorrhage.
" stomach.
" uterus.
Mesenteric disease.
Renal disease.
Entozoa.

Division II. Emaciation of Frame; slight; Countenance of peculiar hues.
From Cardiac disease.
Emphysema.
(Edema pulmonum.
" pleura (hydrothorax).
Malignant diseases.
Isotera.

CLASS V.

Enlargement of Organs, Glands, &c.; Countenance disturbed.

From Goitre.
Tonsillitis.
Cynanche parotidea.
Empyema.
Dropsey.

" general.
" peritoneal.
" hepatic.
" ovarian.
" cardiac.
" mesenteric.
" splenic.
Tympanitis (abdominal).
Tumours.

" ovarian.
" uterine.
" cystic.
" hepatic.
" splenic.
" aneurismal.

Acute rheumatism.

" fibrous.
" synovial.

Hypertrophy cordis

CLASS VI.

Division I. Vascular Excitement; Countenance flushed.

From Erysipelas.
Rubella.
Scarlatina.
" notha.
Urticaria.
Phlebitis.
Rubeoloid fever.

Division II. Vascular Atony; Countenance languid.

From Purpura.
Nythema nodosum.

Division I. Vascular Disturbance; Countenance of peculiar hues.
From Anemia.

Ramollissement.

Otitis, &c.

Tumours.

Arachnitis.

Injuries of the head.

There is no department of semeiology in which so much valuable, precise, and oftentimes infallible information is conveyed to the mind of the experienced medical physiognomist, as in that of cerebral diseases and disturbances. The physiologist is prepared to expect such things when he surveys the human face, and finds in it four muscles, at least, peculiar to man, and which are evidently designed to convey the mute language of expression. (a) These muscles of expression take the lead, it may be said; in exhibiting or portraying all the varied shades, alterations, and lineaments in the physiognomy of disease. It has been truly observed that a practitioner who has a discerning and an experienced eye in medical physiognomy will attain, in many instances, to a readiness of diagnosis and a certainty of prognosis which will astonish persons who have neglected this study.

DISSECTION OF A LARGE SCROTAL HERNIA, WHICH EXTENDED FOUR INCHES BELOW THE KNEES.

By JOSEPH THOMPSON, Esq., Surgeon, Nottingham.

John Harris, aged fifty-four, was admitted to the Union Hospital two years and ten months ago, on account of an immense inguinal hernia of the left side. He was a framework-knitter, of middle stature, pale, and sharp features. About thirty-seven years back he served four years in the militia, but states that he has been of steady habits. There is no proof that any of his relations have been afflicted with rupture. When the tumour, which he ascribes to a fall, first made its appearance about ten or eleven years since, it was about the size of an egg and reducible, he being at that time a corpulent man weighing twelve stones. He did not apply to any surgeon for relief, but put a truss on himself, which produced considerable excoriation and inflammation. About four years ago an abscess formed in the scrotum, which was opened, and afterwards the tumour progressively enlarged up to the time of his admission. He worked for two years after the protrusion, but not within the last eight, during which latter period it has been irreducible. The circumference of the hernia on admission was thirty-two inches, but subsequently there was at intervals a temporary enlargement of it, depending, as he supposed, upon potatoes and pea-soup, which he occasionally took as a part of his diet, which caused diarrhoea and flatulence. He never was habitually constive. The penis has been concealed in the tumour for five years. From the time of his being received into the hospital he has had frequent attacks of purging, and latterly he has exhibited unequivocal symptoms of granular degeneration of the kidneys. The former has for some weeks been incessant, and the symptoms altogether have been such as to indicate ulceration of the colon, of which, coupled with Bright's disease, the poor man died on May 6.

Post-mortem twenty-four hours after Death.—Body not greatly emaciated; lower extremities oedematous, particularly the right; ankylosis of the left knee. I determined upon examining, first, the cavity of the abdomen; second, the hernial tumour. There was a layer of adipose tissue, three quarters of an inch thick, in front of the abdominal muscles. The viscera being exposed, the stomach was found to occupy a more perpendicular position than usual, being, together with a portion of the transverse colon, dragged by the omentum towards the left abdominal ring. The small intestines—small in quantity—inclined to the left side, being seated chiefly behind the

omentum. A part of the cecum had passed into the hernial sac; the other, with the ascending and a portion of the transverse colon, remained in the cavity of the abdomen. The rectum, where it usually joins the colon, turned forwards through the internal ring. A ligature having been passed round these parts at the abdominal ring, they were removed and measured, the small intestines being five feet five inches long, the large twenty inches. There was not any disease of the small, but some solitary ulcerations upon the mucous membrane of the large, intestines. The omentum was much thickened, owing to a great quantity of fat deposited between its layers. The appendices epiploicae were large and numerous. Venous congestion of the stomach at the cardiac extremity, and slight inflammation at the pyloric, with softening of the mucous membrane throughout. Spleen and pancreas in a healthy condition. The left kidney was situated in the left hypochondriac region, its upper extremity reaching as high as the seventh rib. It was increased to two and a half times its natural size, flabby, easily stripped of its capsule, beneath which were several serous cysts. The distinction between the cortical and tubular structures scarcely existed; the whole being softened, of a mottled appearance, and granular. The calyces and infundibuli were much dilated, and two small calculi removed from the former. The right was reduced to half its proper size, and presented nearly the same appearance as the left. The liver, of the natural dimensions, was somewhat thickened and rounded at its borders, readily lacerated, and slightly affected with fatty degeneration. The gall-bladder contained a calculus of a black colour, and a considerable quantity of light orange-coloured bile. The bladder contained half a pint of urine. The hernial tumour, which measured thirty-seven inches round its widest part, eighteen and a half round its neck, and thirty two from the abdominal ring in front to the posterior of the neck, reached four inches below the knees. The penis and testicles were completely hidden in its structure. The scrotum was exceedingly thickened and rugose, and in some places indurated and ulcerated from frequent attacks of inflammation. An ulceration existed at the bottom of the tumour anteriorly, and one on its left side, the result of sloughing caused by the weight of the left thigh reposing upon it at this part, the knee being ankylosed, and not permitting of frequent change of position. The veins in the neighbourhood of these ulcerations are of large size, and have often furnished a considerable exudation of serum. They have occasionally burst and given rise to hemorrhage. The hair of the scrotum are distant and scattered. The orifice of the prepuce, eight inches below the symphysis pubis, is situated on the right side of tumour, and from this the raphe extends downwards, dividing the rupture into two unequal parts, four-fifths being on the left and one-fifth on the right side. An incision was now made through all the tissues down to the spermatic fascia from the abdominal ring to the bottom of the tumour. In front, and at the lateral parts of the scrotum below, the distance from the surface to the fascia could not be less than two inches. The scrotum had an indurated feel, and when pressed it could be reduced in thickness owing to the escape of serum with which it was infiltrated. On dissecting aside these parts, so as to expose the spermatic fascia, an abscess was opened at the lower extremity of the incision, and a small teacupful of dark offensive matter escaped. The intestines did not open into the abscess, but formed the upper boundary of it, and were so adherent one to another as to prevent the escape of the purulent matter, although in absolute contact with it. The left posterior, inferior, and anterior walls of this abscess were formed by the thickened scrotum, whilst the right was formed by a hydrocele of the left tunica vaginalis. These had not been discovered during life, owing to the immensely thickened state of the scrotum, and the want of irregularity of the tumour. The fascia spermatica having been ex-

(a) These four are the corrugator supercilii; the triangularis; the depressor alae nasi; the nasalis labii superioris; together with the anterior portion of the occipito-frontalis.

posed along the anterior and lateral parts, was slit up and found much increased in strength and thickness. The cremaster muscle was very much developed, and sent its fibres from the lower border of the internal oblique and transversalis muscles downwards and inwards for a great distance, whilst those at the inner side of the ring commencing at the insertion of the above-named muscles were more distinct, took a more curved direction outwards, and did not extend so far. The naked eye could not discern whether or not these fibres were continuous one with the other. The fascia transversalis was also very dense and strong, and could be separated from the sac with the greatest ease. When the latter had been opened from the top to the bottom, and its contents brought into view, it was found adherent to the enclosed parts through the lower half of its extent, but in its upper half no adhesions were found at the ring or elsewhere. Although the fingers could not be passed behind the parts protruded, this depended upon the meso-colon being reflected so as to be continuous with the sac. The fingers could be placed between the colon, which was behind, and the small intestines; and between the latter and the omentum which was in front, and extended from the ring to the bottom of the sac. All the parts were behind the omentum, and when that was divided, one part was turned upwards and the other downwards, but before the latter could be accomplished it had to be torn from the sac in front and the intestines behind. The small intestines, as well as being adherent to the sac and omentum, were glued to each other and to the colon; and in this way the abscess which has been mentioned was bounded above, without allowing of any escape of matter between the convolutions of the intestines, although the sac was absent at this part. The relative position of the parts protruded was as follows:—Beginning at the outer side of the abdominal ring posteriorly, a portion of the transverse colon descended along the outer side of the sac behind the intestines to the bottom, and after having crossed over the abscess ascended to the ring, which it entered posterior to the cæcum and small bowels, to become continuous with the rectum. By this course it formed a sort of basin in which were lodged the small intestines and the lower half of the cæcum, the latter being near the ring at the right side. The small intestines, together with the portion of the cæcum, were eight feet one inch long, and free from disease. The mesentery, at its furthest point from the bowel, was three quarters of an inch thick. The colon was forty inches long, had much fat connected with it, but not in the form of appendices; and its lining membrane presented ulcerations of different shapes and sizes, almost innumerable. The hydrocele, which has been alluded to, was about fourteen inches below the ring, and the spermatic chord behind the hernia, inclining much towards the right side. The right testis reached about ten inches below the ring, being agated on the right of the tumour, inclining backwards. The penis, as well as all these parts, was so completely buried in the scrotum as not to be distinguishable by the touch, extending obliquely inwards in the direction of the opening of the prepuce already described. Between the latter and the glans penis there was a considerable distance; and the glans, from the pressure it had sustained, was very small, and covered by its peculiar secretion. It was at one time suspected that it would be necessary to use the catheter; but, under the circumstances, it would have been difficult to have reached the bladder, or even the orifice of the urethra, without sitting up the prepuce; and, if that had been done, perhaps even then it would have been difficult to pass an instrument into the bladder. The fist could, without difficulty, be passed through the inguinal canal into the abdomen. The epigastric artery ran along the inner side of the neck of the sac.

It is not my intention to make many observations upon this case; I wish, however, to remark, that much more than half of the large

and small intestines had passed into the hernial sac; that the course of the ingesta would be, first, from the stomach into the duodenum, then along the five feet five inches of small intestine contained in the abdominal cavity; second, through the internal abdominal ring and the eight feet one inch of small intestine, and the half of the cæcum contained in the hernial sac; third, into the cavity of the abdomen, through the other half of the cæcum and the twenty inches of colon existing in that cavity, and again through the inner ring, along the forty inches of colon in the hernia, until at last it arrived at the same part again, to become continuous with the rectum. I ought to mention that the apparent shortness of the intestinal tube is accounted for as follows:—The mesentery and mesocolon were not cut close to the bowels, and the latter not stretched before the measurements were taken. This, however, is of little consequence, as it does not interfere with the relative proportion of intestines contained in the abdomen and hernia. The action of the abdominal muscles could only influence the parts included within the abdomen; and the process of defecation, so far, at least, as the contents of the hernial sac were concerned, must have been accomplished solely by the peristaltic action of the bowels, unless it were possible the hypertrophied condition of the scrotum could enable it to assist in the performance of that function. When all the adhesions are considered, together with the extraordinary course and altered situation of the intestines, it is truly wonderful how the latter relieved themselves with so much facility. That the thickened state of the scrotum was a provision of nature against injury to the protruded parts I think there can be no doubt, and it is to be regretted that no portion of the dartos was reserved, that a minute examination might have been made of its peculiar structure. When it is considered that the rupture reached below the knee, it will be at once perceived what an elongation must have taken place of the superior and inferior mesenteric arteries and veins, &c. &c. Many questions of importance suggest themselves in connection with this case, but I forbear making any further comments, as my chief object has been to give publicity to it, without taking up too much of your valuable space with observations which everybody can make as well or better than myself.

In conclusion, I am indebted to my friend Dr. Stiff for the history of the case.
Nottingham, August, 1847.

ON THE ELECTRIC THEORY OF LIFE. By R. BRANDON, Esq.

Since we can take electricity from human beings by isolating them, it is fair to infer that this fluid forms part of the animal economy; and as many, if not all, of the phenomena of life can be produced by electricity or by galvanism, I think it not unreasonable to explain life by the electric theory. It is much better to have definite ideas on given subjects, and I, for one, would much rather believe that the nervous fluid was electric, than search after an ideal liquid called the nervous fluid. May not the nerves be conductors of electricity? and is not thought electric? The brain is the organ for the transmission of the electric fluid, which it receives from the nerves or conductors; and from the external senses and the expressed ideas or words is the reflection of the impressions daguerrotyped on the brain, and made comprehensible to others by means of language. Friction is one means of generating electricity; and the friction between the human organs is the cause of life, for let these be quiescent for any lengthened period, and life becomes latent; but death does not ensue until decomposition takes place, and to prevent this you must restore the play between the various organs necessary for life, which we may oftentimes effect when we least hope for success, if we will but try to place a subject apparently dead under the same cir-

cumstances as one who is alive. Thus a man apparently dead, if from disease or from drowning, or any other cause, wants motion, circulation, respiration, animal heat, we can give motion by galvanism, blood by transfusion, respiration by artificial respiration, and animal heat is evolved by this process and by the external and internal application of caloric, by means of a hot-bath at 110°, and by stimulants, such as brandy, &c. We are much too apt to think our patients dead, because they are apparently so, and I am inclined to think the safer method would be to apply means for the recovery of all those who are thought to be dead, in order to prevent premature burial, and to discover those who are only brought down to a state of syncope by the exhausting effects of perhaps a protracted disorder, too little food, and too much treatment. Simple inspection is not enough to determine which body may be recovered, and which may not, since many have been left for dead in whom life was but latent, and who have afterwards recovered through accidental causes, or by the remedial power of Nature's cure, viz., time. Some of the symptoms of insanity may, I think, be explained by means of the electric theory: thus, when the circulation becomes over active in the brain, the friction between the blood-vessels and their contents, and between the blood-vessels and the brain, becomes more considerable, and, more electricity being evolved, more ideas are produced, the external senses become excited, convey impressions over quickly to the brain; and these, daguerrotyped on the brain, are conducted to the organs of speech by the nerves, to be expressed by words: thence patients with too active a circulation in the brain have too many impressions conveyed to the world within (the brain), and are always expressing these impressions by words. The cure, in such cases, is obvious, namely, to calm the troubled circulation by kind moral treatment, by diet, by a temporary seclusion from the world and its troubles, and, when necessary, by a special treatment to the brain, or other organ reacting on this: for insanity is not always a disease of the brain at first, but is often so in very protracted cases, where there is much violence, many illusions, and constant utterance of words without apparent meaning. Haslem thinks that a loose state of the scalp, in the posterior part of the head, indicates effusion of liquid between the membranes of the brain. I believe that affections of this organ were much more common formerly, when chains and the whip were used, than at present: since, now we try a more rational method of cure, and endeavour to control the patient by obtaining his confidence, and by a moral and somewhat non-restraint system, rather than by coercion. I regret to state that I have heard the fact asserted, on good authority, that there is much cruelty used in some establishments in Belgium; and my informants, being Belgians, are not likely to deceive me. The brain is the centre of all impressions, and it receives sensation by means of electric vibrations produced by the contact of the electricity conveyed the nerves and external senses with that electric fluid which is contained within the skull, as in a Leyden jar a slight shock is produced by the contact of a connecting rod, which explodes the contained fluid by means well known to chemists and all scientific persons. The animal part of ourselves is but the medium for the transmission of the electric or nervous fluid; whenever the electricity of the external is brought in contact with the electricity contained within the cavities of our bodies, electric shocks are produced, which are conveyed by the nerves to the brain, where another series of electric vibrations takes place, producing various phenomena, according to their intensity. To make myself more nearly understood, I will state my belief that man resembles a Leyden jar inasmuch that he is loaded with electricity, and that, when these different kinds of electricity come in contact, electric vibrations take place, which are some-

veyed by the nerves to the brain. When the shock is violent, it produces by its intensity what we call pain; and this impression is conveyed oftentimes to the organs of speech, and the fact is expressed by words; and to the extremities, causing certain movements indicative of suffering. Impressions may be conveyed from the brain to the extremities, or vice versa. When there is too much blood in the head, and the nervous matter is pressed upon by this fluid, there is diminished sensibility, because there is less space for the electric fluid. There is but a given amount of surface in the brain, and when this is pressed upon by blood, it is not in a state for the production of those electric vibrations which produce sensation. The pressure of too much blood in the head is the cause of diminished sensibility in the insens; and the cure is obvious. I should consider this diminished sensibility as an indication of the necessity of applying a few leeches to the head or neck—a treatment which could do no harm, and would oftentimes produce much good.

Hanwell, Aug. 30.

ON THE EXTRACTION OF FOREIGN SUBSTANCES IN THE OESOPHAGUS.

By M. FONTAN (de Chazelle).

Two pieces of money and a wedge of wood have been easily removed from the oesophagus, by means of an instrument invented by M. Fontan, constructed and used in the following manner:—The shaft is a small piece of whalebone, of forty or fifty centimètres long, one and a half wide, and three millimètres thick; its extreme end cut like a carp's tongue, and perforated, two millimètres from the edge, with a red-hot needle. This hole receives a piece of red thread rather longer than the whalebone; the part three millimètres from the hole, nearly to the end, should be thinner, in order to render it more flexible. When used the operator draws the thread rather tightly, to make the whalebone concave, to agree with the convexity of the root of the tongue. When it reaches the pharynx, he loosens the thread to give to the stem its natural rectitude, and to avoid by this means contact with the epiglottis. He then raises his hand to give the instrument a little swinging movement, and proceeds to search for the obstruction, which is easily discovered by a slight resistance and a rather dull sound. At this period it is sufficient to press the instrument gently, so as to make it pass between the obstruction and the hinder division of the pharynx. When it is thought that the whalebone has passed this body by two or three centimètres, we withdraw the thread until the whalebone comes into the form of a V, so as to surround the foreign body. It then only remains to withdraw the instrument and hold the thread tightly, to keep the whalebone in a bow, to prevent injury to the mucous membrane of the oesophagus and the muscular fibres, which appear to contract as the instrument is being withdrawn.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of Aug. 23; M. BRONGNIART in the Chair.

PURULENT OPHTHALMIA OF INFANTS.—M. Velpeau read a communication which he had received from Dr. Chassaignac, surgeon of the Foundling Hospital. Purulent ophthalmia had been hitherto almost constantly followed with loss of vision, in that establishment. Since the method employed by M. Chassaignac had been resorted to, this unfortunate termination had not been observed in a single case. On examination of the diseased eyes, M. Chassaignac had recognized that the mucous surface of the tunica sclerotica, and of the internal aspect of the eyelids, was covered with a transparent false membrane, which became opaque by immersion

into water, and which aggravated the disease, first, by acting as a foreign body, and secondly, by interfering with the immediate application of remedies. The membrane might be removed with a small forceps, and the rapidity of the cure was very much hastened by continued irrigations and douches of water on the eyeball and on the inner face of the eyelids.

ACADEMY OF MEDICINE.

Meeting of Aug. 24; M. BROIN in the Chair.

ELECTION OF A SECRETAIRE PERPETUEL.—Almost the entire meeting was taken up by this election; the ballot-box was carried round three times, and the final result was the election of M. Dubois (d'Amiens) by a majority of 56 votes against M. Roger Collard, who obtained 43. Meeting adjourned at half-past five.

TREATMENT OF POLYPI OF THE PHARYNX AND NASAL FOSSE.—M. Velpeau asserts that the fibrous polypi of these regions do not require to be removed in totality in order to be radically cured. It is sufficient, in the professor's opinion, to disorganize a portion of the tumour, and what is left mortifies spontaneously in a short time. In one case of nasal polypus extending as far back as the fauces, M. Velpeau crushed only the most prominent part of the tumour; and in another case of pharyngeal polypus, the professor was satisfied with the destruction of one third of the growth: in both these cases the rest of the tumours were totally destroyed by consecutive gangrene. During a couple of days after operation, some signs of inflammation show themselves in the vicinity of the crushed polypus, which becomes the seat of suppuration of a putrid nature, and in a space of time varying from six to twelve days the tumour falls away. Thus the destruction of the fibrous polypi of the pharynx, or of the nasal fosse, has become, in M. Velpeau's hands, an operation of a very simple nature, and unattended with risk; it is, besides, much more rapidly performed, and less painful, than the other methods hitherto resorted to for the fulfilment of the same object.—*Bulletin de Thérapeutique.*

TREATMENT OF VARICOSE VEINS BY GALVANOPUNCTURE.

The success of this method in the treatment of small aneurisms naturally suggested its application to the cure of varicose veins. The following instances of success we extract from the *Journal des Connaissances Méd.-Chirurgicales*.

CASE I.—A peasant, aged thirty-six, was admitted into the hospital of Milan on July 6, 1846; he was affected with numerous and large varicose veins on both inferior extremities. Electricity was applied in the following manner: a roller bandage was applied from the toes to the knee, and another from the groin to the knee, leaving a space of about four inches between the two bandages. The patient stood during the operation, and two platina needles were each introduced through one of the venous coils, and their extremity left free in the cavity of the veins. Two other needles were also introduced, in a parallel direction with the former, but not passed into the veins. One wire (zinc) was placed in communication with the needles penetrating the veins, the other wire (copper) with the external needles. During thirty minutes the galvanic pile was thrown into action, the patient complaining now and then of a burning sensation. A red areola formed round the punctures towards the end of the operation. After twenty-four hours, clots were felt in the veins, and acquired greater solidity during the ensuing days; but the patient declined going through the same process again, and was dismissed on the 13th, leaving the surgeons in doubt as to the ultimate success of the attempt.

CASE II.—On the 2nd of August a miller, fifty, was received into the hospital of Varese, suffering so much from varicose veins that he had been obliged to interrupt his labour. The internal saphena presented nodes varying from the size of a walnut to that of a pea. On the 3rd, one of the tumours was submitted to the gal-

twelve minutes, and was removed in three days; after ten operations all the varicose veins disappeared. Dr. Bectani and Dr. Milani were the operators.

D. M'CARTHY, D.M.P.

Pregnancy and Parturition during the Existence of Cancer Uteri.—Dr. Joseph Eve, Professor of Obstetrics in the Medical College of Georgia, gives the history of a remarkable case of pregnancy and parturition in connection with cancer of the uterus. The patient was young, apparently healthy, and robust, and the process of gestation was conducted most perfectly, notwithstanding undoubted evidence of cancerous ulceration from the discharge and characteristic fetor. On the first examination, at the period of labour, the head was found low in the pelvis; the mouth of the womb extinguished, except a small portion, which had a humid, hard, rough, unnatural feel. The labour was far more difficult, painful, and protracted, than her two preceding ones. The child was eventually expelled by the unaided efforts of nature. At this time there was noticed a small very similar to that of cancer of the womb. Two or three months previously to her confinement she consulted her medical attendant relative to a sanguine discharge to which she had been subject for some time; and it was feared that it might depend on placenta prævia, but which was afterwards discovered to be in consequence of carcinoma. Since then it has been ascertained that she experienced severe pains in the region of the uterus, and such unusual sensations that caused her for a long time to doubt whether she was pregnant. After confinement she had an offensive discharge per vaginam, and, upon examination, an offensive scirrhus enlargement of the neck of the uterus was discovered. The extent of the ulceration could not be satisfactorily discovered by the speculum, as from violent hysterical convulsion it was obliged to be removed before a proper inspection could be made. She was put on the internal use of proto-iodide of mercury, chloride of soda being used as a vaginal injection, and sulphate of morphia given when in pain. In a fortnight the cancerous ulceration had made most frightful and destructive progress, having involved not only the posterior lip but the hinder part of the cervix. A lotion of nitrate of silver was prescribed, with a view of correcting the fetor and improving the condition of the ulcer. After this she became subject to most alarming and exhausting hemorrhages at each menstrual period; suffering also severe lancinating pains, her strength rapidly failing, and her body becoming emaciated. Two weeks subsequently it was found that the disorganization was proceeding with great rapidity. After the destruction of the posterior lip, posterior portion of the neck, and body of the uterus, the ulceration extended through the vagina and rectum, allowing the feces to pass from the latter through the former, and must have involved even the sacral plexus of nerves, from the excruciating paroxysmal pains she suffered in that region. For seven months longer she continued to linger in the most painful and deplorable condition, experiencing sufferings indescribably severe. There is no account of a post-mortem inspection. Pregnancy and cancer have each a prejudicial influence over the other—the former hastening the progress and fatal termination of the latter; while this in the majority of cases causes either abortion, or the death of the fetus when delivery occurs at the full term. Of 120 cases of malignant disease of the uterus, referred to by Mr. Lever, abortion occurred in 40 per cent.; in 27 of delivery, 15 children were born dead, 10 living, and in 2 the result was not known. The child in the present case was a fine and healthy one, and lived.

Gunsnot Wound in the Left Axilla.—A man belonging to the United States' army was shot accidentally by another who was immediately opposite to him, and about one hundred and twenty yards distant. The man was not seen by the surgeon until the evening of the second day after the accident, when no signs of the ball

could be detected by the most careful examination. The patient was then labouring under the most distressing dyspnoea. When first shot he expectorated blood freely, but when seen the next day, there was neither cough nor expectoration. The ball had entered at the left axilla. The left cavity of the chest seemed to be half full of blood, and on raising the man, and turning him on the left side, at least half a pint of blood escaped through the wound. The following day he was bled twice, and the treatment was strictly antiphlogistic. About a week after, the track of the ball was plainly to be seen. After passing through the chest it made its exit half way, and just below the spine of the scapula; thence glancing inwards and downwards, lodged near the spinous process of the twelfth dorsal vertebra, where it was extracted. The man lived, and, from a robust and healthy individual, became thin and pale, and is troubled with a constant cough.

Treatment of Surgical Affections by Elevation of the Diseased Parts.—M. Gerdy has for some time been in the habit of treating certain inflammatory affections by placing the limb, or part, in such a position as to favour the return of blood to the heart. The plan has this advantage, that it does not exclude the application of the usual means of treatment; but in many cases it is sufficient itself to effect a cure. M. Gerdy raises the end of the bed on which the patient lies by placing a chair under it, thus raising the foot upon the summit of an inclined plane. Once so placed, and care being taken that no injurious pressure is exerted, the patient must not move from the position, even to satisfy natural wants, for he may destroy in a few minutes all the benefits which have been obtained by whole days of repose. The advantage of this plan of treatment is not, however, confined to inflammation, but is equally serviceable in ulcers, uterine hemorrhages, and varicose veins. In many instances of the latter disease, elevation alone of the limb has been completely successful. The utility of this plan is incontestible in varicocele. The following conclusions have been arrived at:—1. That the elevation of the diseased part is able, without the intervention of other therapeutical measures, to cut short certain inflammations, if it be employed sufficiently early. 2. That in phlegmon it relieves pain by diminishing the quantity of blood in the part. 3. That it advances the cure of engorgements and chronic profluvia of the uterus. 4. That certain hemorrhages may be suspended by it. 5. That it is able to cure certain ulcers of the lower extremities. 6. That varices and hemorrhoids are advantageously modified by elevation. 7. That, where it is not sufficient in itself to effect a cure, it is always a potent auxiliary.

Turpeth Mineral as an Emetic in Croup.—Dr. Hubbard, of Hallowell, Maine, U.S., recommends very highly the use of the yellow sulphate of mercury as an emetic in croup, on the ground of its promptness and certainty, its never producing catharsis, and its not being followed by prostration like that occasioned by tartar emetic. Its emetic operation usually continues from an hour to an hour and a half, accompanied and followed by none of the distressing nausea, prostration, and depletion of antimony. From two to three grains may be given to a child two years old, and repeated in ten or fifteen minutes, until emesis is produced. If the first dose fails, the second usually acts as soon as it touches the stomach.

Beneficial Effects of the Sulphate of Quinine.—Dr. Baldwin, of Montgomery, U.S., in attending a young man suffering from remittent fever of quotidian type, ordered thirty-six grains of sulphate of quinine, to be divided into twelve pills, two of which were to be taken every two hours. The patient, however, in two hours took the whole of them, and, from having been taciturn and anxious about his situation, became cheerful and seemed to enjoy a fine flow of spirits. The pulse was slightly increased in frequency, and he laughed immoderately at his recovery. He knew every person in the neighbourhood of the place, and related the most interesting events that had transpired

before, and yet would make statements, and insist on their truth, which were known to be only the workings of his excited imagination. Five hours after taking the dose he was less disposed to talk, and complained of fullness about his head. In twenty-four hours the effects of the medicine seemed to have subsided; he still complained, however, of disagreeable feeling about his head, recollected the strange fancies that had possessed him, and became rather depressed in spirits. He took no more quinine, and had no other paroxysm of fever, though his convalescence was protracted, suffering more or less from disordered bowels for eight or ten days, and complaining of disagreeable sensations in his head. There was great similarity of the action of quinine in this case to that of protoxide of nitrogen.

Adipocere.—Dr. Blakeman, of New York, in company with some other members of the profession, inspected the body of a woman which had been interred in one of the burying-grounds of the city for seventeen years. The coffin in which it had been enclosed was very little affected by inhumation. The form of the cadaver was perfectly preserved. The extremity of the nose was gone, and the features of the face partially discernible. The arms, which were placed along the sides, had become much compressed by the swelling of the body, and the hands had broken off at the wrists. The remains of one hand, upon the right side of the abdomen, were distinctly visible, and the fore finger, with its nail, was entire. The rotundity of the breast was perfect; the abdomen flattened, as if by compression against the lid of the coffin. The left foot, like the hands, had separated from the ankle. The shape of the thighs was remarkably preserved. The shroud adhered to the body, and was not decayed, though discoloured. The body presented a greenish hue, from mould with which it was covered, and a fresher coat of pure white had been deposited upon it since its exposure to the air. The cap was distinct upon the head, and the bow of black ribbon on one side, somewhat faded, remained. A piece about a foot square was cut out of the abdominal walls so as to expose the cavity. The knife passed easily through their substance, which was found to consist entirely of a yellowish, cheesy substance. The thin layer of abdominal muscles could be distinguished, similarly converted beneath the adipose layer, which was very thick. The inner surface of the abdominal cavity was smooth. The viscera, and a large lump of adipocere, lay at the bottom. The diaphragm was distinctly seen. Below it, and towards the left, much shrunk and condensed, and having the consistence, somewhat, of lung, lay the liver. The stomach, having its natural form and a nacerated appearance, was distinctly visible; and some portions of the colon, collapsed and membranous, were discoverable. An odour resembling that of gum ammoniac exhaled from the body. The soil in which the coffin was interred was sandy and not moist; and two bodies of children buried over it, and others in the vicinity, were in a complete state of disorganization. The subject was sixty-nine years of age, very fat, and weighed 170 pounds. The disease of which she died was not known.

Action of the Glands of the Stomach.—Julius Vogel, quoted in "The British and Foreign Medical Review," says, the gastric glands present certain peculiarities: the product of their secretion so far coincides with the saliva that it consists of an aqueous fluid, with salts and extractive matters, whilst the remains of dissolved gland-cells testify to the presence of protein, consumed and modified by organization. But the gastric juice exhibits the peculiarity of containing a free acid. The manner in which this acid is conveyed to it is so much the more difficult of explanation that we do not even know clearly its chemical character: for, while it was formerly regarded as hydrochloric acid, it is supposed by more recent investigators to be lactic, combined with a little phosphoric acid; which latter, however, simply owes its origin to

the action of the lactic acid upon the alkaline phosphates simultaneously present. By what means is the presence of the free acid brought about? The answer to this question is difficult, and many conjectures may be hazarded on the subject. The acid undoubtedly owes its origin to the blood, and the process of its formation may be owing to the decomposition of some of the salts (alkaline lactates or chlorides) of that fluid by the cells of the gastric glands which retain the acid, while the alkali returns by diffusion into the blood. As the cells gradually become broken up and dissolved, the acid is liberated and mixes with the gastric juice.

Diaphragmatic Hernia.—This consists, says Mehliss, in "The British and Foreign Medical Review," in the formation of a diverticulum or hernial sack, the short end of which is directed upwards within the thorax, whilst the base opens into the abdomen. The sack is, for the most part, diminutive, but occasionally exceedingly capacious, and it always contains a smaller or greater portion of abdominal viscera. The parietes of the sack sometimes consist of the serous investment of the diaphragm only—the muscular fibres having merely undergone separation; at other times the walls include the muscular fibres, and the hernia is simply a partial distention of the organ alone; with its serous coats. In the majority of cases these hernias have been accidentally discovered during the dissection of bodies, without any symptoms having even denoted their existence. In a few of the recorded instances, however, the enormous mass of abdominal organs, both hollow and parenchymatous, contained in the sack cannot have failed to produce the greatest disturbance to the organs, both of circulation and respiration. There are examples of a violent blow struck against the abdomen sufficing to produce fatal hernia at the anterior portion of the diaphragm, situate between the sternal and costal portions, where no muscular fibres occur, and the two serous sacks, therefore, meet. Hernia occurring in the body of the diaphragm is probably, in most instances, dependent on congenital malformation.
